Abstract. This study reviews the species of the tribe Smicronychini Seidlitz, 1891 found in southern Africa. In total, 18 species are recognized in this region, 12 of them being described as new (*Sharpia madibai* sp. nov., *Afrosmicronyx cynii* sp. nov., *A. louwi* sp. nov., *A. marshalli* sp. nov., *A. nebulosipennis* sp. nov., *Smicronyx pseudocoecus* sp. nov., *S. australis* sp. nov., *S. drakensbergensis* sp. nov., *S. gracilipes* sp. nov., *S. paucisquamis* sp. nov., *S. san* sp. nov., *S. similis* sp. nov.). The following genera and species are newly reported from this area: *Afrosmicronyx* Hustache, 1935; *Sharpia* Tournier, 1873; *Smicronyx pauperculus* Wollaston, 1864; *S. albosquamosus* Wollaston, 1854 and *S. namibicus* Haran, 2018. New host plant taxa and plant associations for the tribe are reported among the families Gentianaceae Juss., Orobanchaceae Vent. and Convolvulaceae Juss. A key to species and images of the habitus of adults and male genitalia are provided.

Keywords. *Sharpia*, *Smicronyx*, *Afrosmicronyx*, new species, biological control.

Haran J.M. 2021. The Smicronychini of southern Africa (Coleoptera, Curculionidae): Review of the tribe and description of 12 new species. *European Journal of Taxonomy* 735: 34–73.
<https://doi.org/10.5852/ejt.2021.735.1239>

Introduction

The weevil fauna of southern African is still unevenly known (Proches 2003). While large-bodied groups have received attention from early and more recent authors (i.e., Marshall 1946; Louw 1995), the smaller-bodied groups (Borovec & Skuhrovec 2018), in particular among the subfamily Curculioninae Latreille, 1802, have scarcely been studied (but see Caldara *et al.* 2009). As a result, the few taxonomic revisions of genera conducted in the smaller-bodied clades usually lead to the discovery of a large number of new species (Caldara 1989, 1996). Following the revisions of several genera among the Afrotropical Smicronychini Seidlitz, 1891 (Haran & Perrin 2017; Haran 2018) the diversity of this tribe from southern Africa was explored.

Very little was known about the Smicronychini from the southern African region (here considered below the 20th parallel South). An initial species, *Smicronyx fallax* (Gyllenhal, 1836) was described from “Caffraria”, an area currently including broadly the Eastern Cape Province of the Republic of South

Africa. More recently, a second species distributed at several places within tropical Africa (*S. zonatus* Haran, 2018) was described based on specimens from the Western Cape Province of the Republic of South Africa. Lastly, in recent years, attempts were made to introduce *S. lutulentus* Dietz, 1894 from North America to South Africa for biological control of the Asteraceous weed *Parthenium hysterophorus* Linnaeus, 1753 (Strathie *et al.* 2011).

Knowledge on the diversity of Smicronychini in southern Africa is needed to ensure that native and introduced species can be effectively distinguished, especially when the establishment of introduced species is tracked based on field sampling. Due to their associations with parasitic and hemi-parasitic plants of crops in the Afrotropical region (genera *Orobanche* Linnaeus, 1753, *Cuscuta* Linnaeus, 1753, *Striga* Loureiro, 1790, *Buchnera* Linnaeus, 1753) the genera of this tribe are of potential interest for biocontrol. The aim of this study was therefore to revise the Smicronychini of southern Africa. About 400 specimens obtained from Natural History Museums and newly collected ones were examined using a standard taxonomic approach based on morphology and molecular diagnostic tools. A key, a description or a diagnosis of each species is provided with images of the habitus of adults and penis of males.

Material and Methods

Abbreviations of depositories

Preparation and photographs

The abdomens of adult specimens were extracted and digested in KOH to obtain clean preparations of genital structures, as these are commonly used to distinguish between species in Smicronychini (Zumpt 1936; Péricart 1957; Haran *et al.* 2017; Haran & Perrin 2017; Haran 2018). The illustration of male structures was restricted to the body of the penis, as it shows substantial variation between species of *Smicronyx*. The endophallic structures of male genitalia and external genitalia of the female (spermatheca and sternum VIII) are not described or illustrated, as examination of these structures did not reveal any significant or phylogenetically informative differences between most of the species from the area examined. The habitus and male genitalia were photographed using a Keyence® VHX5000 imaging system. Extended depth-of-field images were obtained using the software of the imaging station. Measurements were taken with an optical micrometer. Body length refers to the distance from the apical margin of the head (excluding the rostrum) to the apex of the elytra. Rostrum length refers to the distance between the apical margin of the eyes and the apex of mandibles. The ratio of width to length (w/l) was measured at the widest point of the prothorax, the elytra and the penis. The length of the elytra was measured between the anterior part of the scutellum and the apex of the elytra. The length of the penis was measured between the base of the penis body (apodemes excluded) and the apex. The terminology used follows Lyal (2019). Scales are important features for distinguishing between *Smicronyx* species, but they are fragile and may be partly lacking on some individuals. The diagnoses

and descriptions in this study refer to fresh specimens with an entire vestiture. The identity of the species described before recent revisions was established using the original description (*S. fallax* and *S. lutulentus*), or examination of type material and reference collections (*S. albosquamosus* Wollaston, 1854 and *S. pauperculus* Wollaston, 1864). Neotype designation follows ICZN (1999) article 75. Data on each label of holotypes are reported between single quotation marks, each line of the label is separated by a slash, additional information to help label interpretation is given in square brackets.

Molecular analysis

A specimen per species was sequenced for the standard barcode fragment when fresh material could be obtained. DNA was extracted from entire specimens using a DNeasy Blood & Tissue kit (Qiagen, Hilden, Germany). PCR amplifications were carried out using the standard primers for barcoding (mitochondrial cytochrome c oxidase subunit I, *COI*) for invertebrates: LCO1490: 5'-GGTCAACAAATCATAAAGATATTGG-3' and HCO2198: 5'-TAAACTTCAGGGTGACCAAAAAATCA-3' (Folmer *et al.* 1994). PCR reactions were carried out on a Mastercycler® Nexus (Eppendorf, Hamburg, Germany) in a volume of 10 µl of PCR mix containing 5 µl of Multiplex Master Mix (Qiagen, Hilden, Germany), 0.8 µl of primers (Forward and Reverse at 2 µM) and 2 µl of DNA. The PCR conditions were as follows: initial DNA denaturation at 94°C for 15 minutes, followed by ten cycles of 30 s each at 94°C, 1 min at 60–50°C (touchdown of -1°C per cycle) and 30 s at 70°C, followed by 30 cycles of 30 s at 94°C, 1 min at 55°C, and 1 min at 72°C with a final extension of 20 min at 72°C. The PCR products were sequenced by Eurofins Genomics (<http://www.eurofinsgenomics.eu/>). All voucher specimens sequenced were mounted, dried and deposited at the Centre de Biologie pour la Gestion des Populations, Montpellier, France (CBGP, CIRAD collection <https://doi.org/10.15454/D6XAKL>). Barcode sequences were aligned using CodonCode Aligner ver. 3.7.1. (CodonCode Corporation, Centerville, MA, USA), and checked to identify the presence of pseudogenes using standard detection methods (Haran *et al.* 2015). Sequences were subjected to a BLAST (implemented in the NCBI platform <https://www.ncbi.nlm.nih.gov/>) to compare them to the existing sequences of species of *Smicronyx* (Haran *et al.* 2017; Haran 2018). Uncorrected p-distance values of pairwise genetic distances between species were computed with Mega 7 (Kumar *et al.* 2016).

Figs 1A, 3A, 5A; Table 1

Differential diagnosis

Sharpia madibai sp. nov. is mostly similar to *S. soluta* Faust, 1885, a species widely distributed in the Mediterranean region on *Convolvulus dorycnium* Linnaeus, 1759 (Friedman 2017). It can be distinguished from it by the absence of spots of white scales in the middle of interstria 2–3 (*S. soluta* shows such spots), and by the shape of the penis very elongate [ratio w/l: 0.15] with a series of small

Description

BODY LENGTH. 2.4–3.0 mm.

COLOUR. Body integument reddish brown; vestiture consisting of imbricated scales, polygonal, shiny, completely concealing the integument, scales dark brown, pale brown and white, with white scales generally condensed along the median line of prothorax, forming a white band in the middle of 4th interstria and near apex of interstria 1–3.

HEAD. Rostrum as long as head + prothorax and regularly downcurved in lateral view, thicker than protibiae in dorsal view, densely punctuate and striate (♂), smooth with small punctures in apical half (♀), basal $\frac{2}{3}$ (♂) or basal half (♀) of upper side bearing dense cover of pale brown scales, upper side of scrobes forming a carina slightly expanding basally near eyes; transverse furrow at base of rostrum narrow, shiny, bare of scales, with two spots of erect white scales on side near eyes; head capsule short, densely covered with scales; antennae inserted at apical $\frac{1}{3}$ (♂) or near middle of length (♀) with segment 1 longer than 2 + 3, 4 isodiametric, segments 5–7 wider than long.

PROTHORAX. Slightly wider than long (ratio w/l: 1.02), widest in basal $\frac{1}{3}$ of length, greatly narrowed at apex, integument concealed with rounded, almost hexagonal scales, and few scattered suberect, elongate, white scales oriented toward the centre of prothorax.

ELYTRA. Sides subparallel in basal $\frac{2}{3}$, slightly expanding toward middle of length, widest near middle (ratio w/l: 0.71), humeri raised; declivital callosities on interval 5 present but weak, followed by a depression; striae narrow, $\frac{1}{2}$ – $\frac{2}{3}$ width of interstriae; interstriae flat, shiny, bearing two series of imbricated scales and one series of suberect elongate scales; scutellum very small.

ABDOMEN. Underside densely covered with white and grey, elliptical, overlapping scales.

LEGS. Femora clavate, unarmed; tibiae straight, unarmed, slightly bisinuate on ventral side; claws equal in length.

GENITALIA. Body of penis very elongate (ratio w/l: 0.15), 2 × as long as apodemes, sides slightly convex, widest near basal $\frac{1}{3}$, straight and converging toward apex in apical $\frac{2}{3}$, apex rounded, curvature in lateral view weak, mainly in basal half (Fig. 5A).

Life history

Host plant unknown, adults collected by sweeping vegetation. *Sharpia* Tournier, 1873 spp. are commonly collected on perennial non-parasitic Convolvulaceae.

Distribution

Namibia, Republic of South Africa (Kruger National Park, Northern Cape Province).

Genus *Afrosmicronyx* Hustache, 1935

Afrosmicronyx cycnii sp. nov.

urn:lsid:zoobank.org:act:13BC63BD-16FB-4F63-A4C1-183285E1BAA9

Figs 1B, 3B, 5B; Table 1

Differential diagnosis

This species is mostly similar to *Afrosmicronyx angolanus* (Hustache, 1935), a species distributed in Angola (Haran & Perrin 2017). The two species can be distinguished by the protibial tooth (well developed in *A. angolanus*, absent or very small in *A. cycnii* sp. nov.), the scales on the elytra (dense, rounded, with a copper shine in *A. angolanus*, scattered, elliptic and greyish in *A. cycnii* sp. nov.), and the shape of the penis (sides rounded in *A. angolanus*, sides straight and regularly converging from base to apex in *A. cycnii* sp. nov.).

Etymology

This species is named in reference to the genus of the host plant *Cycnium adonense* E. Mey. ex Benth., on which the type series was collected.

Material examined

Holotype

REPUBLIC OF SOUTH AFRICA • 1 ♂; “South Africa Tvl. [Mpumalanga Province]; Schoemanskloof valley; m 1200 - 25.19'S 30.40'E; 14.XI.1988 - Colonnelli” / “On; *Cycnium; adonense* E. Mey. Ex. Benth.” / “HOLOTYPE; *Afrosmicronyx cycnii*; Haran 2021”; SAMC.

Paratypes

Description

BODY LENGTH. 2.9–3.7 mm.

COLOUR. Body integument black; vestiture consisting of short rounded recumbent scales, longer than wide, black, not concealing the integument.

HEAD. Rostrum longer than head + prothorax in lateral view, moderately downcurved, thicker than protibia in middle in dorsal view, densely punctuate and striate, punctures and striae smoother near apex, basal ¼ of upper side bearing small suberect black setae, upper side of scrobes forming a carina with a small tooth basally near eyes; transverse furrow at base of rostrum shiny, bare of scales; head capsule short, bare of scales; antennae with segment 1 as long as 2 + 3, 4–6 isodiametric, segment 7 wider than long.

PROTHORAX. Isodiametric (ratio w/l: 1), widest at basal ⅓, greatly narrowed at apex, densely and coarsely punctuate, median line smooth and slightly raised.

ELYTRA. Sides subparallel in basal ⅓, slightly expanding toward middle of length, widest after middle (ratio w/l: 0.65), humeri raised; declivital callosities on interval 5 present but weak, followed by a depression, striae narrow, ¼ width of interstriae; interstriae flat, shiny, bearing 2–3 ill-defined series of scales; scutellum small, shiny, bare of scales.

Fig. 1. Habitus of species of Smicronychini from southern Africa (Part 1). **A.** *Sharpia madibai* sp. nov., ♂, holotype (SAMC). **B.** *Afrosmicronyx cynnii* sp. nov., ♂, holotype (SAMC). **C.** *Afrosmicronyx louwi* sp. nov., ♂, holotype (SAMC). **D.** *Afrosmicronyx marshalli* sp. nov., ♂, holotype (SANC). **E.** *Afrosmicronyx nebulosipennis* sp. nov., ♂, holotype (BMNH). **F.** *Smicronyx gracilipes* sp. nov., ♀, holotype (SAMC). **G.** *Smicronyx similis* sp. nov., ♂, holotype (SANC). **H.** *Smicronyx pseudocoeceus* sp. nov., ♂, holotype (SAMC). **I.** *Smicronyx paucisquamis* sp. nov., ♂, holotype (SAMC). **J.** *Smicronyx fallax* (Gyllenhal, 1836), ♂, neotype (NHRS). **K.** *Smicronyx australis* sp. nov., ♂, holotype (SAMC). **L.** *Smicronyx pauperculus* Wollaston, 1864, ♂, specimen from Tanzania. Scale bars: 1 mm.

ABDOMEN. Underside covered with greyish scattered scales, 3 × as long as wide, with a metallic-copper shine; ventrite 1 shorter than 2.

LEGS. Femora clavate, armed with one ventral tooth; tibiae straight, bearing a moderate thickening ventrally, sometimes almost forming a tooth on protibiae, facing femoral tooth when legs are folded; claws equal in length.

GENITALIA. Body of penis short (ratio w/l: 0.42), as long as apodemes, sides straight, regularly converging from base to apex, apex rounded, curvature in lateral view regular (Fig. 5B).

Fig. 2. Habitus of species of Smicronychini from southern Africa (Part 2). **A.** *Smicronyx san* sp. nov., ♂, holotype (SAMC), bred from *Chironia baccifera* L. **B.** *S. san* sp. nov., ♂, paratype (CBGP), specimen bred from *Orphium frutescens* L. (E. Mey). **C.** *S. san* sp. nov., ♂, paratype (CBGP), specimen bred from *Sebaea* Sol. ex R.Br. sp. **D.** *Smicronyx drakensbergensis* sp. nov., ♂, holotype (TMSA). **E.** *Smicronyx zonatus* Haran, 2018, ♂, paratype (CBGP), specimen from the Western Cape Province of the Republic of South Africa. **F.** *Smicronyx lutulentus* Dietz, 1894, ♂ (CBGP). **G.** *Smicronyx albosquamosus* Wollaston, 1854, ♂ (CBGP), specimen from Israel. **H.** *Smicronyx namibicus* Haran, 2018, ♂ (MNHN), specimen from Tanzania. Scale bars: 1 mm.

Sexual dimorphism

Females are distinguished from males by their rostrum, which is slightly longer, and more downcurved in lateral view.

Life history

All the specimens of this species were collected on *Cycnium adonense* E. Mey. Ex. Benth., 1835 (Orobanchaceae) a hemiparasitic plant parasite of grass. Adults were collected in November in the Republic of South Africa.

Distribution

Republic of South Africa (Mpumalanga Province).

Afrosmicronyx louwi sp. nov.

urn:lsid:zoobank.org:act:90CD8ADD-9841-4742-B4BF-61E6F709EDA0

Figs 1C, 3C, 5C; Table 1

Differential diagnosis

Afrosmicronyx louwi sp. nov. is mostly similar to *A. madagascariensis* Haran, 2018. The two species can be distinguished by their size (body length 3.4–3.6 mm in *A. madagascariensis*, 2.5 mm in *A. louwi* sp. nov.), the protibial tooth (moderately thickened in *A. louwi* sp. nov., strongly thickened tooth in *A. madagascariensis*) and the shape of the penis (sides subparallel, thickened in middle in lateral view in *A. louwi* sp. nov., sides convex, thickness regular in lateral view in *A. madagascariensis*).

Etymology

This species is dedicated to the late Dr. Schalk Louw, for his contribution to the knowledge of southern African weevils.

Material examined

Holotype

REPUBLIC OF SOUTH AFRICA • 1 ♂; “Natal [Kwazulu-Natal Province]; Malvern” / “N. Barkers; 190” “SAM-COL-;A073094” / “HOLOTYPE; *Afrosmicronyx louwi*; Haran 2021”; SAMC.

Description

Male

BODY LENGTH. 2.5 mm.

COLOUR. Body integument black; vestiture consisting of rounded recumbent scales, as long as wide or slightly elliptical, brown and greyish on elytra.

HEAD. Rostrum as long as head + prothorax in lateral view, moderately and regularly downcurved, slightly wider than protibiae in dorsal view, punctate and striate, smooth at apex, covered with scales in basal $\frac{2}{3}$, less densely in apical $\frac{1}{3}$, upper side of scrobes forming a carina with a small tooth basally near eyes, transverse furrow at base of rostrum shiny, bare of scales; antennae black, inserted before apical $\frac{1}{3}$, segment 1 slightly longer than 2 + 3, 4 isodiametric, 5–7 wider than long.

PROTHORAX. Wider than long (ratio w/l: 1.14), widest slightly before middle of length, greatly narrowed at apex, sides rounded; integument shiny, densely granulate; scales brownish and greyish, longer than wide, generally concealing granules, forming two paler bands laterally to the median line.

ELYTRA. Sides moderately convex, straight and expanding apicad in basal $\frac{1}{2}$, rounded in apical $\frac{1}{2}$, widest near middle (ratio w/l: 0.70); humeri raised; striae narrow, interstriae flat, wide and shiny, covered with 2–3 series of aligned scales, apex of interstria 5 with slight declivital callosity, followed by depression; scutellum small but visible.

ABDOMEN. Underside covered with rounded brownish-grey scales, not concealing the integument.

LEGS. Dark brownish, femora clavate, armed with one ventral tooth; tibiae bearing a moderate thickening ventrally, facing femoral tooth when legs are folded; claws equal in length.

GENITALIA. Body of penis elongate (ratio w/l: 0.36), sides parallel, converging near apex, apex rounded, curvature regular in lateral view, thicker in apical half. (Fig. 5C). Female not known.

Life history

Unknown.

Distribution

Republic of South Africa (KwaZulu-Natal Province).

Afrosmicronyx marshalli sp. nov.

urn:lsid:zoobank.org:act:E0C45446-219B-4B9D-8714-3C94C28D3DDF

Figs 1D, 3D, 5D; Table 1

Differential diagnosis

Afrosmicronyx marshalli sp. nov. is mostly similar to *A. angolanus*, a species distributed in Angola and Kenya (Haran & Perrin 2017). The two species can be distinguished from each other by the shape of their prothorax (wider than long in *A. marshalli* sp. nov., isodiametric in *A. angolanus*) and their protibiae (with a thickening at middle in *A. marshalli* sp. nov., armed with an acute tooth in *A. angolanus*).

Etymology

Afrosmicronyx marshalli sp. nov. is dedicated to Sir Guy A. K. Marshall for his outstanding contribution to the knowledge on African weevils and particularly on the southern African fauna.

Material examined

Holotype

REPUBLIC OF SOUTH AFRICA • 1 ♂; “Nr. Belfast; Tvl. [Mpumalanga Province]; 14 Jan. 1963; A L Capener” / “National Coll.; of Insects; Pretoria, S. Afr” / “HOLOTYPE; *Afrosmicronyx marshalli*; Haran 2021”; SANC.

Paratype

REPUBLIC OF SOUTH AFRICA • 1 ♀; same collection data as for holotype; SAMC.

Description

BODY LENGTH. 3.0–3.2 mm.

COLOUR. Body integument black; vestiture consisting of rounded recumbent scales, as long as wide or elliptical, greyish on elytra.

HEAD. Rostrum equal (♂) or slightly longer than head capsule plus prothorax (♀) in lateral view, moderately downcurved, in dorsal view covered with scales only in basal $\frac{1}{3}$, shiny and slightly punctate in apical $\frac{2}{3}$; antennae inserted slightly after middle of length; transverse furrow at base of rostrum shiny, with two spots of whitish semi-erect scales on sides near eyes; head capsule glabrous; eyes flat, subcontiguous ventrally, distance between eyes equal to the width of 1–2 ommatidia; antennal scape slightly bisinuate at base, moderately clavate at apex, segment 1 of funicle elongate, as long as 2 + 3, 3–7 wider than long.

PROTHORAX. Slightly wider than long (ratio w/l: 1.08), widest near middle of length, greatly narrowed at apex, sides strongly rounded; integument shiny, densely granulate; scales greyish, longer than wide.

ELYTRA. Sides convex, widest near middle (ratio w/l: 0.7); humeri raised; striae narrow, interstriae flat, wide and shiny, striae $\frac{1}{3}$ width of interstriae, covered with two or three series of aligned scales, apex of interstria 5 with slight declivital callosity, followed by a depression; scutellum small but visible.

ABDOMEN. Underside covered with elliptical greyish scales, not concealing the integument.

LEGS. Integument black, femora clavate, armed with one ventral tooth; tibiae bearing a thickening (♂) or a tooth (♀) ventrally, facing femoral tooth when legs are folded; claws equal in length.

GENITALIA. Body of penis short (ratio w/l: 0.56), about $0.7\times$ as long as apodemes, sides convex, converging near apex, apex truncate, curvature in lateral view stronger near apex (Fig. 5D).

Life history

Unknown.

Distribution

Republic of South Africa (Mpumalanga Province).

Afrosmicronyx nebulosipennis sp. nov.

urn:lsid:zoobank.org:act:7AF87EB3-BC0C-486C-849B-8A4A1B681A4E

Figs 1E, 3E, 5E; Table 1

Differential diagnosis

Afrosmicronyx nebulosipennis sp. nov. is mostly similar to *A. umbrinus* Hustache, 1940, a species widely distributed from West to East Africa (Anderson & Cox 1997). The body length of *A. nebulosipennis* sp. nov. (3.6–3.8 mm) is slightly shorter than in *A. umbrinus* (3.8–4.0 mm) and its general appearance is more robust. Segment 3 of the antennal funicle is wider than long in *A. nebulosipennis* sp. nov. while it is isodiametric in *A. umbrinus*. The penis in *A. nebulosipennis* sp. nov. is more elongate and its sides more rounded (Fig. 5E) than in *A. umbrinus*.

Etymology

Afrosmicronyx nebulosipennis sp. nov. is named in reference to the ill-defined shades of its elytral vestiture.

Material examined

Holotype

ZIMBABWE • 1 ♂; “Salisbury [Harare]; Oct. 1903; G A K M [Marshall]” / “Pres. By; Imp. Inst. Ent.; BMNH(E) 1996” / “HOLOTYPE; *Afrosmicronyx nebulosipennis*; Haran 2021”; BMNH.

Paratypes

ZIMBABWE • 2 ♂♂, 2 ♀♀; same collection data as for holotype; BMNH.

Description

BODY LENGTH. 3.6–3.8 mm.

COLOUR. Body integument black; vestiture consisting of rounded recumbent scales, elliptical, twice as long as wide, forming grey, brown and/or white, ill-defined transverse bands on elytra.

HEAD. Rostrum distinctly longer than head capsule + prothorax in lateral view, downcurved at base, almost straight in the rest of the length, covered by scales on the upper face only in basal $\frac{1}{2}$ (♂) or in basal $\frac{1}{3}$ (♀); integument punctuate; antennae inserted at apical $\frac{1}{3}$; transverse furrow at base of rostrum covered with whitish scales, with two spots of semi-erect whitish or brownish scales on sides near eyes; head capsule glabrous except near transverse furrow; eyes flat, subcontiguous ventrally, distance between eyes equal or shorter than width of 1–2 ommatidia; antennal scape slightly bisinuate at base, moderately clavate at apex, segment 1 of funicle elongate, as long as 2 + 3, 3–5 isodiametric, 6–7 wider than long.

PROTHORAX. Isodiametric (ratio w/l: 1), widest slightly before middle of length, greatly narrowed at apex, sides strongly rounded; integument shiny, densely granulate; scales brownish, 3 × as long as wide, converging to the median line.

ELYTRA. Sides subparallel in basal half, widest near middle (ratio w/l: 0.74), convex in apical half; humeri raised; striae narrow, interstriae flat, 4 × as wide as striae, integument shiny and rough, covered with two or three series of aligned scales, apex of interstria 5 with a declivital callosity, followed by a depression; base of interstria 3 with a spot of white scales; scutellum rounded, small but visible.

ABDOMEN. Underside covered with elliptical greyish scales, not concealing the integument; ventrite 2 as long as 3–5.

LEGS. Integument black, femora clavate, armed with a strong ventral tooth; tibiae bearing an acute tooth ventrally, before middle of length, facing femoral tooth when legs are folded; claws equal in length.

GENITALIA. Body of penis short (ratio w/l: 0.55), as long as apodemes, sides parallel, apex flat with an acute cuticular expansion, curvature in lateral view moderate and regular (Fig. 5E).

Life history

Unknown.

Distribution

Zimbabwe (Harare).

Genus *Smicronyx* Schoenherr, 1843

Smicronyx gracilipes sp. nov.

urn:lsid:zoobank.org:act:BE18ED2E-7D6F-42C7-8550-59B004B62C95

Figs 1F, 3F; Table 1

Differential diagnosis

Smicronyx gracilipes sp. nov. is closest to *S. guineanus* Voss, 1956, but *S. gracilipes* sp. nov. is lacking or has a very small femoral tooth (well developed in *S. guineanus*), a less dense coating of scales on the elytra (almost concealing the integument in *S. guineanus*). The sequences of the *COI* show that *S. gracilipes* sp. nov. is distinct by 8.7% [GB accession: MT370314] with specimens of *S. guineanus* from Niger.

Etymology

The species epithet refers to the remarkable long and thin legs encountered in this species.

Material examined

Holotype

REPUBLIC OF SOUTH AFRICA • 1 ♀; “Rep. of South Africa; Underberg, [KwaZulu-Natal Province]; 29°346'37.42”S 29°30'00.44”E; 1579 m, 30.xii.2018; J. Haran leg.” / “Beating flowers of; Anacardiaceae; JHAR02024_0101” / “HOLOTYPE; *Smicronyx gracilipes*; Haran 2021”; SAMC.

Description

Female

BODY LENGTH. 2.5 mm.

COLOUR. Body integument black, antennae dark brown; vestiture of elytra made of recumbent scales, elliptic, not overlapping, twice as long as wide, grey, aligned in 2–3 ill-defined series on each interstria;

HEAD. Rostrum slightly longer than head capsule + prothorax in lateral view, moderately downcurved, in dorsal view covered with scarce scales in basal $\frac{1}{3}$ and very short white setae in apical $\frac{2}{3}$, punctate over entire length, smooth at apex; antennae inserted near middle of length; transverse furrow at base of rostrum shiny, with two spots of whitish erect scales on sides near eyes; head capsule glabrous, with slight cover of scales near transverse furrow; eyes flat, subcontiguous ventrally, distance between eyes equal to the width of two ommatidia; antennal scape slightly bisinuate at base, moderately clavate at apex, segment 1 elongate, as long as 2 + 3, 4–5 isodiametric, 6–7 wider than long.

PROTHORAX. Slightly wider than long (ratio w/l: 1.05), widest near middle, sides rounded, narrowed in apical $\frac{1}{4}$; integument smooth, shiny, with small punctures; scales brown, elongate, not concealing the integument, with grey scales forming a pale band along the median line and two on the sides of prothorax.

ELYTRA. Sides slightly convex, widest near middle (w/l ratio: 0.74); humeri raised; striae $\frac{1}{3}$ width of interstriae, interstriae flat, shiny, interstria 5 with a moderate declivital callosity near apex, followed by a slight depression; scutellum small but visible.

ABDOMEN. Underside mostly covered with non-overlapping greyish scales, twice as long as wide.

LEGS. Femora clavate, unarmed or bearing a very small ventral tooth in middle; tibiae straight, unarmed, claws equal in length. Males unknown.

Fig. 3. Head and prothorax in lateral view of species of *Smicronyx* from southern Africa (Part 1). **A.** *Sharpia madibai* sp. nov., ♂, holotype (SAMC). **B.** *Afrosmicronyx cycnii* sp. nov., ♂, holotype (SAMC). **C.** *Afrosmicronyx louwi* sp. nov., ♂, holotype (SAMC). **D.** *Afrosmicronyx marshalli* sp. nov., ♂, holotype (SANC). **E.** *Afrosmicronyx nebulosipennis*, sp. nov., ♂, holotype (BMNH). **F.** *Smicronyx gracilipes* sp. nov., ♀, holotype (SAMC). **G.** *Smicronyx similis* sp. nov., ♂, holotype (SANC). **H.** *Smicronyx pseudocoeceus* sp. nov., ♂, holotype (SAMC). Scale bars: 0.5 mm.

Life history

Host plant unknown. The holotype specimen was collected on flowers of an unidentified Anacardiaceous shrub surrounded by a large grassland. This specimen was collected in December.

Distribution

Republic of South Africa (KwaZulu-Natal Province).

Fig. 4. Head and prothorax in lateral view of species of *Smicronyx* from southern Africa (Part 2). **A.** *Smicronyx paucisquamis* sp. nov., ♂, holotype (SAMC). **B.** *Smicronyx fallax* (Gyllenhal, 1836), ♂, neotype (NHRS). **C.** *Smicronyx australis* sp. nov., ♂, holotype (SAMC). **D.** *Smicronyx san* sp. nov., ♂, bred from *Chironia baccifera* L., holotype (SAMC). **E.** *Smicronyx drakensbergensis* sp. nov., ♂, holotype (TMSA). **F.** *Smicronyx lutulentus* Dietz, 1894, ♂ (CBGP). Scale bars: 0.5 mm.

***Smicronyx similis* sp. nov.**

urn:lsid:zoobank.org:act:14428DD9-227D-41C6-9062-C95EBF458451

Figs 1G, 3G, 5F; Table 1

Differential diagnosis

Smicronyx similis sp. nov. is mostly similar to *S. guineanus* Voss, 1956, a species widely distributed in tropical Africa. The two species can be distinguished by their general appearance, which is more robust in *S. similis* sp. nov. The second segment of the funicle is isodiametric in *S. similis* sp. nov. while it is distinctly longer than wide in *S. guineanus*, the elytra are wider in *S. similis* sp. nov. than in *S. guineanus* (ratio w/l: 0.68 and 0.58 respectively), and the integument of the prothorax of *S. similis* sp. nov. is more coarsely punctate than in *S. guineanus*. The body of the penis in *S. similis* sp. nov. is also thicker and less narrowed in the middle than in *S. guineanus*. In southern Africa, *S. similis* sp. nov. is closest to *S. gracilipes* sp. nov., but the latter species has distinctly longer legs and rostrum and a finely punctate prothoracic integument (coarsely granulate in *S. similis* sp. nov.).

Etymology

The species name ‘similis’ refers to the similar appearance of this species with *S. guineanus*, which is a very widespread and abundant species in tropical Africa.

REPUBLIC OF SOUTH AFRICA • 1 ♂; “S. Afr.; N Cape Prov.; Tswalu Nat. Res. 1162 m; 27.18S-22.26E” / “14.2.2005; E-Y [Endrödy-Younga leg.]; 3644; general [collecting] at Gosa lodge; Leg. M. Burger, R. Müller” / “HOLOTYPE; *Smicronyx similis*; Haran 2021”; SANC.

Paratype

ZIMBABWE • 1 ♀; Sebakwe; 1903; D. Dods leg.; SAM-COL-A073093; SAMC.

Description

BODY LENGTH. 2.5 mm.

COLOUR. Body integument black, shiny, antennae and legs reddish; vestiture of elytra with scattered, recumbent, brownish and whitish, rounded or elliptic scales, forming two ill-defined series on each interstria.

HEAD. Rostrum slightly longer than head capsule + prothorax, moderately downcurved in lateral view, slightly longer and more downcurved in ♀ than in ♂, covered with scarce whitish scales dorsally (♂) or scales only in basal ¼ (♀), shiny and slightly punctate at apex (♂) or at apical ⅔ (♀); antennae inserted slightly after middle of length (♀) or at apical ⅓ (♂); transverse furrow at base of rostrum shiny, with two spots of whitish semi-erect scales on sides near eyes; head capsule glabrous, with slight cover of scales near transverse furrow; eyes flat, subcontiguous ventrally, distance between eyes equal to the width of 1–2 ommatidia; antennal scape slightly bisinuate at base, moderately clavate at apex, segment 1 of funicle elongate, slightly longer than 2 + 3, 4–7 wider than long.

PROTHORAX. Isodiametric (w/l ratio: 1), widest before middle, sides strongly rounded, narrowed in apical 1/4; integument densely and strongly granulate, shiny.

ELYTRA. Sides slightly convex, widest near middle of length (w/l ratio: 0.68); humeri raised; interstriae flat, shiny, ½–⅓ × as wide as striae, interstria 5 with a moderate declivital callosity near apex, followed by a slight depression; scutellum small but visible.

ABDOMEN. Underside mostly covered with non-overlapping greyish scales, twice as long as wide.

LEGS. Femora clavate, armed with a small ventral tooth in middle; tibiae straight, unarmed; claws equal in length.

GENITALIA. Body of penis elongate (w/l ratio: 0.23), 2 × longer than apodemes, sides sub-parallel in basal 1/3, narrowed near middle of length, spatulate in apical 1/3, apex slightly acuminate, curvature in lateral view regular (Fig. 5F).

Life history

Unknown.

Distribution

Republic of South Africa (Northern Cape Province), Zimbabwe.

Smicronyx pseudocoevus sp. nov.

urn:lsid:zoobank.org:act:FC3639AF-2419-4EBD-A3AF-2F6480677DE8

Figs 1H, 3H, 5G, 6C; Table 1

Differential diagnosis

Smicronyx pseudocoevus sp. nov. is closest to the Palaearctic species *S. coecus* (Reich, 1797). These species can be distinguished by their claws, which are very slightly unequal in length in *S. pseudocoevus* sp. nov. while they are very distinctly unequal in *S. coecus*. The two species also show a p-distance of 8.7% on *COI* (GB accession: MT370315 / KC784156). In the Republic of South Africa, *S. pseudocoevus* sp. nov. is closest to *S. paucisquamis* sp. nov., a species found in Limpopo Province. *S. pseudocoevus* sp. nov. shows a denser elytral vestiture (Fig. 1H–I) and a more sclerified body of the penis (Fig. 5G–H) than *S. paucisquamis* sp. nov..

Etymology

Named in reference to the similar appearance of this species and *S. coecus* (Reich, 1797).

Description

BODY LENGTH. 1.8–2.0 mm.

COLOUR. Body integument entirely black, shiny, mostly bare of scales; vestiture of elytra consisting of white recumbent, elliptical, scales twice as long as wide, grouped in ill-defined transverse bands, a spot on humeri and a longitudinal strip at base of interstria 3; each interstria with series of recumbent, white setae.

HEAD. Rostrum slightly longer than head + prothorax in lateral view, strongly downcurved in basal half, less downcurved in apical half (Fig. 3H), dorsal face punctate, covered with suberect whitish setae forming four distinct series in basal $\frac{2}{3}$ and two spots near eyes, apical $\frac{1}{3}$ glabrous; transverse furrow at base of rostrum shiny, bare of scales; head capsule glabrous; eyes flat, contiguous on ventral side; scape of antennae straight, slightly and regularly widening toward apex, clavate at apical $\frac{1}{3}$, segment 1 of funicle elongate, as long as 2 + 3, 4–7 × wider than long.

PROTHORAX. As long as wide (ratio w/l: 1), widest near middle of length, narrowed at apex, sides rounded; integument punctate and granulous, punctures forming concentric circles at basal half; scales white, elongate, rare, mostly present along apical margin, and forming a small spot near scutellum.

ELYTRA. Sides rounded, widest near middle of length (ratio w/l: 0.65); humeri raised; striae narrow, interstriae flat, wide, integument slightly reticulate, apex of interstria 5 lacking declivital callosity; scutellum small, bare of scales.

ABDOMEN. Underside mostly covered with overlapping white scales, more condensed on metanepisterna.

LEGS. Covered with whitish semi-erect elongate scales; femora clavate, unarmed; tibiae straight on external side, slightly bisinuate ventrally at basal $\frac{1}{3}$; claws slightly unequal in length.

GENITALIA. Body of penis elongate (ratio w/l: 0.28), 3 × as long as apodemes, sides sub-parallel, slightly expanding from middle of length to apical $\frac{1}{5}$, converging apicad, acuminate at apex, curvature in lateral view moderate and regular, tapering at apex (Fig. 5G).

Sexual dimorphism

Females are distinguished from males by their rostrum, which is more downcurved in apical half in lateral view, and by the antennal insertion which is near middle of length (near apical $\frac{1}{3}$ in males).

Life history

Adults of *S. pseudocoecus* sp. nov. were collected on *Cuscuta nitida* E. Mey ex Choisy, 1842 (Fig. 6C–D) and other unidentified species of *Cuscuta*. Most *Cuscuta* sp. are red-listed endangered species in the Republic of South Africa. Adults were collected in January, March, September and November.

Distribution

Republic of South Africa (Western Cape Province).

Smicronyx paucisquamis sp. nov.

urn:lsid:zoobank.org:act:445D4B93-E3FD-4A72-A0E0-81C75252CC47

Figs 1I, 4A, 5H; Table 1

Differential diagnosis

Smicronyx paucisquamis sp. nov. is closest to *S. pseudocoecus* sp. nov.. See differential diagnosis under that species for diagnostic traits.

Etymology

Smicronyx paucisquamis sp. nov. is named in reference to the very limited number of scales found on its elytra compared to other species in the genus.

Material examined

Holotype

REPUBLIC OF SOUTH AFRICA • 1 ♂; “Rep. of South Africa; Haenertsburg [Limpopo Province]; 23°56.361’S 29°57.037’E; 1380 m, 7.ii.2019; J. Haran leg.”/“On *Cuscuta* sp.; JHAR02167”/“HOLOTYPE; *Smicronyx paucisquamis*; Haran 2021”; SAMC.

Paratypes

REPUBLIC OF SOUTH AFRICA • 1 ♀; same collection data as for holotype; ethanol coll. CBGP • 1 ♀; Mpumalanga Province, God’s window; 24°54.396’ S, 30°51.650’ E; 6 Feb. 2019; J. Haran leg.; beating *Cuscuta* sp.; JHAR02168; ethanol coll. CBGP.

Description

BODY LENGTH. 2.0–2.2 mm.

COLOUR. Body integument entirely black, shiny, mostly bare of scales; vestiture of elytra consisting of white recumbent, elliptical, scales more than twice as long as wide, grouped into spots at base of interstria 3, basal $\frac{1}{3}$ of interstriae 4–5 and middle of length of interstriae 3–5; each interstria with a series of short, recumbent, white setae.

HEAD. Rostrum as long as head + prothorax in lateral view, downcurved near base, less downcurved in apical half (Fig. 4A); dorsal face punctate, covered with suberect whitish setae forming four distinct series in basal $\frac{2}{3}$ and two spots near eyes, apical $\frac{1}{3}$ glabrous; transverse furrow at base of rostrum shiny, bare of scales; head capsule glabrous; eyes flat, sub-contiguous on ventral side, space between them wider than the diameter of two ommatidia; scape of antennae slightly bisinuate, regularly widening toward apex, clavate in apical $\frac{1}{3}$, segment 1 of funicle elongate, as long as 2 + 3, 4–7 wider than long.

PROTHORAX. Isodiametric (ratio w/l: 1), widest near middle of length, narrowed at apex, sides rounded; integument with large punctures, diameter of punctures wider than distance between punctures; scales

whitish, elongate, semi-erect, not concealing the integument, mostly present at base of median line near scutellum and on sides of prothorax.

ELYTRA. Sides moderately rounded, widest near middle of length (ratio w/l: 0.66); humeri raised; striae narrow, interstriae flat, wide, 4–5 × as wide as striae, integument shiny, slightly reticulate, apex of interstria 5 with a very moderate declivital callosity; scutellum small, covered with short whitish scales.

ABDOMEN. Underside mostly covered with overlapping white scales, more condensed on metanepisterna.

LEGS. Covered with whitish, recumbent, elongate scales; femora clavate, armed with a very small ventral tooth usually concealed by scales; tibiae straight on external side, slightly bisinuate ventrally; claws equal in length.

GENITALIA. Body of penis elongate (ratio w/l: 0.44), as long as apodemes, sides sub-parallel, slightly expanding from base to apex, converging near apex, truncate at apex, curvature in lateral view moderate and regular, tapering near apex (Fig. 5H).

Sexual dimorphism

Females are distinguished from males by their rostrum, which is slightly longer, and covered with scales only in basal $\frac{1}{3}$ (in basal $\frac{1}{2}$ in males).

Life history

Adults were found in February on an unidentified *Cuscuta* sp.

Distribution

Republic of South Africa (Limpopo and Mpumalanga provinces).

Smicronyx fallax (Gyllenhal, 1863)

Figs 1J, 4B, 5I, 6A; Table 1

Micronyx fallax Gyllenhal, 1836: 427.

Smicronyx fallax (Gyllenhal, 1836) [Schoenherr 1843].

Differential diagnosis

Of the southern African Smicronychini, *Smicronyx fallax* is closely related to *S. albosquamosus*, which may be found in sympatry with this species. They can be distinguished by the shape of their prothorax (isodiametric in *S. fallax*, wider than long in *S. albosquamosus*) and their claws (equal in length in *S. fallax*, unequal in *S. albosquamosus* in most specimens). These species show an interspecific genetic distance of 12.3% for the barcode fragment.

ZIMBABWE • 1 ♂; Matopo, Maleme Dam; 30 Jan. 1963; J. Weir leg.; BMNH.

Redescription

BODY LENGTH. 2.0–2.1 mm.

COLOUR. Body integument entirely black, shiny; vestiture of elytra consisting of whitish and brownish, recumbent, elliptical scales, twice as long as wide; whitish scales forming two ill-defined, oblique bands from humeri to apical $\frac{2}{3}$ of elytral suture and a spot on declivital callosities.

HEAD. Rostrum longer than head + prothorax in lateral view, almost straight (Fig. 4B), dorsal face punctate, covered with suberect whitish scales forming four distinct series in basal $\frac{2}{3}$ and two spots near eyes, apical $\frac{1}{3}$ bearing scattered white setae; transverse furrow at base of rostrum shiny, bare of scales; head capsule glabrous; eyes flat, sub-contiguous on ventral side; scape of antennae slightly bisinuate, slightly and regularly widening toward apex, not clavate at apex, segment 1 of funicle elongate, longer than 2 + 3, 2 square, 3–7 wider than long.

PROTHORAX. Isodiametric (ratio w/l: 1), widest near middle of length, sides moderately rounded, not greatly narrowed at apex; integument punctate and granulous, punctures forming weak concentric circles in basal $\frac{1}{2}$; scales whitish and brownish, elongate, mostly condensed along the median line and on the sides.

ELYTRA. Sides subparallel in basal $\frac{2}{3}$ of length, rounded in apical $\frac{1}{3}$, widest near middle of length (ratio w/l: 0.70); humeri raised; striae narrow, interstriae flat, wide, 4× as wide as striae, integument shiny, slightly reticulate, apex of interstria 5 with a very slight declivital callosity; scutellum small, bare of scales.

ABDOMEN. Underside mostly covered with non-overlapping greyish scales, not condensed on metanepisterna.

LEGS. Covered with whitish, semi-erect, elongate scales; femora clavate, armed with a tiny ventral tooth, usually concealed with scales; tibiae straight on external side, slightly bisinuate ventrally; claws equal in

length. Genitalia. Body of penis elongate (ratio w/l: 0.33), $1.3 \times$ as long as apodemes, sides sub-parallel, broadly rounded at apex, curvature in lateral view moderate and regular, tapering at apex (Fig. 5I).

Sexual dimorphism

Females are distinguished from males by their rostrum, which is slightly longer, and covered with scales only in basal $\frac{1}{4}$ (in basal $\frac{1}{3}$ in males).

Life history

All recently collected specimens of this species were found on dodders (*Cuscuta* spp.) including the introduced weed *Cuscuta campestris* Yunck, 1932 (Fig. 6A–B). Labels indicate that this species might be collected with light traps (UV light). Adults were collected from October to March.

Distribution

Smicronyx fallax is widely distributed in the subtropical and desert areas of southern Africa. It has been recorded from Namibia to Zimbabwe, and in the Gauteng, KwaZulu-Natal, Limpopo, Mpumalanga and Orange provinces of the Republic of South Africa.

Remarks

The type specimen of *S. fallax* was deposited by Gyllenhal in the collection of Ecklon & Zeyer (Gyllenhal 1836), currently lost. In the absence of further information about this type, and in order to stabilize the taxonomy in this genus, a neotype was designated based on the description of this species. Gyllenhal described *S. fallax* as a species very closely related to the Palaearctic taxon *S. jungermanniae* Reich, 1797. This description corresponded very well to the specimens used to re-describe this species, both regarding external and internal morphology. In addition, *COI* sequences obtained from these specimens (JHAR01630_0101-1694_0101 [GB accession: MT370316-17]) showed that they are closest to *S. jungermanniae* out of all the species of *Smicronyx* for which a barcode sequence is available (uncorrected p-distance of 7.0%). The neotype (here designated) was designated for a male specimen from a population from the western side of KwaZulu-Natal Province in the Republic of South Africa, which is close to the original type locality of *S. fallax* (“Caffraria”, probably corresponding to the Eastern Cape Province). Three male and nine unsexed specimens stored in ethanol from this series were deposited in the institutions CBGP, SAMC and SANC.

Smicronyx australis sp. nov.

urn:lsid:zoobank.org:act:11BB79AF-69BD-4596-B063-01C2E7782E04

Figs 1K, 4C, 5J; Table 1

Differential diagnosis

Smicronyx australis sp. nov. is closest to *S. pauperculus*, a species widely distributed in the Mediterranean region and in Africa, including the Republic of South Africa. The two species can be distinguished by the colour of their integument (elytra black in *S. australis* sp. nov., at least partly red in *S. pauperculus*). The sequences of *COI* of *S. australis* sp. nov. (GB accession: MT370318) showed an interspecific p-distance of 3% with specimens of *S. pauperculus* from the Near East and Canary Islands (Genbank accessions: KU942318 and KU942313, respectively).

Etymology

Smicronyx australis sp. nov. is named in reference to the southern distribution of this species, compared to the wide distribution of its neighbour species *S. pauperculus*.

Description

BODY LENGTH. 1.9–2.0 mm.

COLOUR. Body integument entirely black, shiny, femora and tibiae reddish in middle; vestiture of elytra consisting of whitish and brownish recumbent elliptical scales, more than twice as long as wide; whitish scales forming ill-defined transverse bands and a spot on prothorax and elytra near scutellum.

HEAD. Rostrum as long as head capsule + prothorax in lateral view, moderately downcurved (Fig. 4C); dorsal face weakly punctate, covered with suberect whitish scales forming 4 more-or-less distinct series in basal $\frac{2}{3}$ (♂) or $\frac{1}{3}$ (♀), more condensed near eyes, apical $\frac{1}{3}$ bearing scattered white setae; transverse furrow at base of rostrum shiny, bare of scales; head capsule glabrous; eyes flat, sub-contiguous on ventral side, separated by a distance as wide as the width of 1 ommatidium; scape of antennae very slightly bisinuate, regularly widening toward apex, clavate at apex, segment 1 of funicle elongate, slightly longer than 2 + 3, segments 2–7 transverse, segment 7 more than twice as wide as long.

PROTHORAX. Isodiametric (ratio w/l: 1), widest slightly before middle of length, sides moderately rounded, narrowed at apex; integument punctuate and granulous; scales whitish and brownish, elongate, mostly oriented toward the median line.

ELYTRA. Sides subparallel in basal $\frac{2}{3}$, rounded in apical $\frac{1}{3}$, widest near middle of length (ratio w/l: 0.70); humeri raised; striae narrow, interstriae flat, 3–4 × as wide as striae, integument slightly reticulate, apex of interstria 5 with a very moderate callosity; scutellum small, bare of scales.

ABDOMEN. Underside mostly covered with non-overlapping whitish scales, not condensed on metanepisterna.

LEGS. Covered with whitish semi-erect elongate scales; femora clavate, bearing a minute ventral tooth usually hidden by scales; tibiae straight on external side, slightly bisinuate ventrally at basal third; claws equal in length.

GENITALIA. Body of penis short (ratio w/l: 0.60), $0.6\times$ as long as apodemes, sides sub-parallel or slightly expanding apicad, apex truncate, curvature in lateral view moderate and regular (Fig. 5J); endophallus sclerified, forming longitudinal striae at base of body in dorsal view.

Sexual dimorphism

Females are distinguished from males by their rostrum, which is slightly longer, and covered with scales only in basal $\frac{1}{3}$ (in basal $\frac{2}{3}$ in males).

Life history

This species was collected on stems and flowers of *Cuscuta nitida* (Fig. 6D) and other *Cuscuta* spp. Adult specimens were also collected by light trap and by beating fynbos bushes. Adult collection times ranged from August to February.

Distribution

This species is distributed in the Gauteng and Western Cape provinces of the Republic of South Africa.

Remarks

Slight differences in the external and internal morphology and the genetic distances between these species enabled *S. australis* sp. nov. to be distinguished as a distinct species. The black specimens of *S. pauperculus* reported previously (Haran 2018) correspond to *S. australis* sp. nov.

Smicronyx pauperculus Wollaston, 1864

Figs 1L, 5K; Table 1

Smicronyx pauperculus Wollaston, 1864: 317.

Differential diagnosis

Of the southern African Smicronychini, *S. pauperculus* can be distinguished by the red colour of integuments and the absence of a wide transverse band on its elytra.

Material examined

REPUBLIC OF SOUTH AFRICA • 6 ♂♂, 7 ♀♀; Gauteng Province, Pretoria; 25.45 S, 28.10 E; 21 Mar. 1989; S. Naser leg.; SANC • 2 ♂♂, 1 ♀; Pretoria, Reitondale; 4 Apr. 2001; S. NAMIBIA • 1 ♂; Weldevrede Guest Farm; 24.10 S, 15.58 E; alt. 1105 m; 11–13 Feb. 2010; R. Müller leg.; at light; TMSA.

Lectotype

See Haran (2018).

Diagnosis

BODY LENGTH. 1.9–2.0 mm.

COLOUR. Body integument reddish, except rostrum, antennae, prothorax, suture of elytra and tarsi, which are usually black; vestiture of elytra generally consisting of elongate brownish scales, recumbent, not concealing integument, and whitish scales, thicker, forming transverse patches.

HEAD. Rostrum moderately and regularly downcurved in lateral view, longer than head capsule + prothorax.

PROTHORAX. Isodiametric (w/l ratio: 1), sides rounded in basal half, constricted apically, widest slightly behind middle, with median line of whitish scales, mostly visible near scutellum.

ELYTRA. Subparallel in basal two thirds (w/l ratio: 0.65), rounded toward apex in apical third.

LEGS. Femora moderately clavate, armed with a small but distinct ventral tooth, tibiae straight; claws equal in length.

GENITALIA. Body of penis moderately elongate (w/l ratio: 0.60), $0.6 \times$ as long as apodemes, sides straight, subparallel, apex truncate, moderately and regularly curved in lateral view (Fig. 5K); endophallus slightly sclerified, not forming any longitudinal striae at base of body in dorsal view.

Life history

This species is known to feed on flowers of *Cuscuta campestris* (Anderson 1974; Haran *et al.* 2017) developing on plants of open and disturbed agricultural areas. It is often recorded by light trapping. In sub-Saharan Africa, adults were collected almost all year round (February–May, July–September, November–December).

Distribution

Smicronyx pauperculus is widely distributed in the Mediterranean region (Caldara 2013; Haran *et al.* 2017). In sub-Saharan Africa, it has been recorded in West (Mali) and East Africa (Kenya, Tanzania) (Haran 2018) and is newly reported here from southern Africa (Republic of South Africa [Gauteng and Limpopo and Mpumalanga provinces] and Namibia).

Remarks

The identity of this species was established based on the examination of the lectotype as reported by Haran (2018). In southern Africa, this species is closest to its sister species *S. australis* sp. nov.; see differential diagnosis and remark sections on that species for diagnostic traits.

Smicronyx san sp. nov.

urn:lsid:zoobank.org:act:F652DB37-9106-483C-A89F-9F2375C52910

Figs 2A–C, 4D, 5L, 6E; Table 1

Differential diagnosis

In the Republic of South Africa, *S. san* sp. nov. is closest to *S. drakensbergensis* sp. nov.; it can be distinguished from this species by the coating on the elytra (white and brown scales, grey in *S. drakensbergensis* sp. nov.), the ratio of its prothorax (isodiametric, slightly longer than wide in *S. drakensbergensis* sp. nov.), and its shorter penis body (Fig. 5L–M).

Etymology

This species is dedicated to the San people, hunter gatherers whose first traces date back 44 000 years in southern Africa. They left remarkable marks of their presence along the coast in Western Cape Province, where *S. san* sp. nov. forms dense populations due to the local abundance of its host plants.

Description

BODY LENGTH. 1.8–2.0 mm.

COLOUR. Body integument entirely black, shiny; vestiture of elytra consisting of recumbent, elliptical, twice as long as wide, overlapping scales, pale brown with transverse shades of white scales, densely covering but not concealing the integument.

HEAD. Rostrum as long as head + prothorax in lateral view, moderately and regularly downcurved (Fig. 4D), in dorsal view punctate, covered with suberect brown scales in basal $\frac{1}{3}$ – $\frac{1}{2}$, glabrous in apical half; transverse furrow at base of rostrum shiny, bare of scales; head capsule glabrous; eyes flat, close to each other on ventral side, separated by a distance equal to width of 2–3 ommatidia; scape of antennae straight, slightly and regularly widening apicad, clavate in apical $\frac{1}{3}$, segment 1 of funicle elongate, as long as 2 + 3, 4–7 wider than long.

PROTHORAX. Isodiametric (ratio w/l: 1), widest near middle of length, narrowed at apex, sides rounded; integument greatly punctuate and granulous, shiny; scales pale brown, overlapping, usually concentrated on sides, with a spot of white scales near humeri; disc usually bare of scales or with narrow scales not concealing integument, forming a broad longitudinal strip where integument remains visible; median line sometimes bearing a narrow band of brown scales, generally visible at base near scutellum.

ELYTRA. Sides rounded, widest near middle of length (ratio w/l: 0.76); humeri raised; striae narrow, interstriae flat, wide, integument slightly reticulate, apex of interstria 5 lacking declivital callosity; scutellum small, not visible through coating.

ABDOMEN. Underside mostly covered with overlapping pale brown scales, more condensed on metasternum and metanepisterna.

LEGS. Covered with pale brown semi-erect elongate scales; femora clavate, bearing a tiny ventral tooth usually concealed by scales; tibiae straight on external side, slightly bisinuate ventrally at basal third; claws equal in length.

GENITALIA. Body of penis very short (ratio w/l: 1), $0.8\times$ as long as apodemes, sides sub-parallel or slightly expanding from base to apex in basal $\frac{2}{3}$, converging in apical $\frac{1}{3}$, acuminate at apex, curvature in lateral view regular (Fig. 5L).

Sexual dimorphism

Females are distinguished from males by their rostrum, which is slightly longer, and less densely covered with scales in basal $\frac{1}{2}$.

Life history

Smicronyx san sp. nov. develops on various Gentianaceae: *Chironia baccifera* Linnaeus, 1753, *Orphium frutescens* (L) E. Mey., 1838, *Sebaea* spp. including *S. aurea* (L. f.) Roem. & Schult. (Fig. 6E–H). Adults were collected on the ground under its host plant or by beating the plant in February, June, August, October–December.

Distribution

Republic of South Africa (Western Cape Province).

Remarks

Smicronyx san sp. nov. belongs morphologically to the *S. reichi* (Gyllenhal, 1835) species group (Dieckmann 1990), which is associated with Gentianaceae, and shows a much shorter body of the penis than other *Smicronyx* species (Pericart 1957). *S. san* sp. nov. is a polymorphic species, specimens obtained from *Orphium frutescens* (Fig. 2B) are larger and have a less dense coating than specimens developing on *Chironia* (Fig. 2A). Specimens obtained from *Sebaea* have a more elongate body (Fig. 2C) than those on *Chironia*. However, the sequences of the gene *COI* revealed no genetic divergence between populations from each host plant.

Smicronyx drakensbergensis sp. nov.

urn:lsid:zoobank.org:act:0E52BFCE-0C56-411D-A089-EA48704B33C2

Figs 2D, 4E, 5M; Table 1

Differential diagnosis

Smicronyx drakensbergensis sp. nov. belongs to the species group of *S. reichi* and is morphologically closest to *S. san* sp. nov. in southern Africa. See diagnosis and remark sections under that species for diagnostic traits.

Etymology

This species is named in reference to the mountain range where the type series was collected.

Material examined

Holotype

REPUBLIC OF SOUTH AFRICA • 1 ♂; “S. Afr.; Drakensberg [KwaZulu-Natal Province]; Cathedral PkRainbowG [gorges]; 28.57S 29.14E” / “17.i.1997; E-Y; 3257; grassnetting; leg. Endrödy-Younga” / “HOLOTYPE; *Smicronyx drakensbergensis*; Haran 2021”; TMSA.

Paratype

REPUBLIC OF SOUTH AFRICA • 1 ♂; same collection data as for holotype; SAMC.

Description (♂)

BODY LENGTH. 2.0–2.2 mm.

COLOUR. Body integument entirely black, shiny; vestiture of elytra consisting of recumbent, elliptical or rounded, brownish and whitish, overlapping scales, densely covering but not concealing the integument.

HEAD. Rostrum as long as head + prothorax in lateral view, moderately and regularly downcurved (Fig. 3E), in dorsal view punctate, covered with suberect whitish scales in basal $\frac{1}{2}$, glabrous in apical $\frac{1}{2}$; transverse furrow at base of rostrum shiny, bare of scales, with two spots of white erect scales on each side near eyes; head capsule glabrous; eyes flat, close to each other on ventral side, separated by width of 2–3 ommatidia; scape of antennae straight, slightly and regularly widening toward apex, clavate in apical $\frac{1}{3}$, segment 1 of funicle elongate, slightly longer than 2 + 3, 4–7 wider than long.

PROTHORAX. Wider than long (ratio w/l: 1.07), widest before middle of length, narrowed at apex, sides moderately rounded; integument greatly punctuate and granulous, shiny; scales greyish, overlapping, not concealing integument.

ELYTRA. Sides rounded, widest near middle of length (ratio w/l: 0.73); humeri raised; striae narrow, $\frac{1}{2}$ – $\frac{1}{3}$ as wide as interstriae, interstriae flat, wide, integument shiny, slightly reticulate, apex of interstria 5 with very small declivital callosity; scutellum small, not visible through coating.

ABDOMEN. Underside mostly covered with overlapping greyish scales, more condensed on metasternum and metanepisterna.

LEGS. Covered with pale brown and greyish semi-erect, elongate scales; femora clavate, bearing a tiny ventral tooth usually concealed by scales; tibiae straight on external side, slightly bisinuate ventrally at basal third; claws equal in length.

GENITALIA. Body of penis short (ratio w/l: 0.80), 2.2 × shorter than apodemes, sides sub-parallel, apex acuminate, curvature in lateral view regular (Fig. 5M). Female unknown.

Life history

Host plant unknown. Adults were collected in January.

Distribution

Republic of South Africa (KwaZulu-Natal Province).

Smicronyx zonatus Haran, 2018
Figs 2E, 5N; Table 1

Smicronyx zonatus Haran, 2018: 280.

Differential diagnosis

Of the African Smicronychini, *S. zonatus* can be easily distinguished from other species by its reddish integument and its white transverse band on the elytra (Haran, 2018).

Material examined

REPUBLIC OF SOUTH AFRICA • 1 ♀; Mpumalanga Province, Kruger National Park, Skukuza Reserve Camp; 24.59 S, 31.35 E; 1 Mar. 1995; Endrödy-Younga leg.; UV light trap; SANC • 1 ♂, 1 ♀; KwaZulu-Natal, Eshowe; Jul. 1926; R.E. Turner leg.; BMNH • 1 ♂; Drakensberg, Van Reenen; 1–22 Jan. 1927; R.E. Turner leg.; BMNH.

Other material

See Haran (2018).

ZAMBIA • 1 ♂; Liua Plains; 29 Nov. 2003; Deschodt and Groenewald leg.; at light; SANC.

Diagnosis

BODY LENGTH. 2.0–2.5 mm.

COLOUR. Body integument reddish, except rostrum, antennae, prothorax, suture of elytra and tarsi, which are usually black; vestiture of elytra generally consisting of elliptical, rounded scales or slightly longer than wide, recumbent, overlapping and almost concealing integument; scales brown with patches of white and a few black spots along the basal half of interstriae 1–3, and a large transverse white band between middle of elytra length and apical ¼.

HEAD. Rostrum as long as head capsule + prothorax in lateral view, greatly downcurved

PROTHORAX. Wider than long (w/l ratio: 1.08), sides rounded, widest slightly before middle of length.

ELYTRA. Subparallel in basal ½, rounded in apical ½ (w/l ratio: 0.73).

LEGS. Femora and tibiae covered with whitish and pale brown semi-erect, elongate scales; femora greatly clavate, armed with a small but distinct ventral tooth.

GENITALIA. Body of penis elongate (w/l ratio: 0.37), 1.5 × longer than apodemes, subparallel, rounded at apex, in lateral view regularly narrowing from base to apex (Fig. 5N).

Life history

Recently collected specimens from the Republic of South Africa (Stellenbosch, Western Cape Province) were found on a small unidentified Orobanchaceae (near the genus *Euphrasia* Linnaeus, 1753), a hemiparasite of Cyperaceae found at low elevation in wet areas near ponds (Fig. 6I–J). Adults were collected in January–March, May, July and November.

Distribution

Democratic Republic of Congo, Liberia, Republic of South Africa (KwaZulu-Natal, Mpumalanga and Western Cape provinces), Zambia (Haran 2018).

Smicronyx lutulentus Dietz, 1894
Figs 2F, 4F, 5O; Table 1

Smicronyx lutulentus Dietz, 1894: 170.

Differential diagnosis

Smicronyx lutulentus is morphologically similar to *S. fallax* and *S. albosquamosus*. It can be distinguished from these species by its elytra pattern, bearing broad and rounded scales, and its short penis body.

Material examined

REPUBLIC OF SOUTH AFRICA • 6 specs; KwaZulu-Natal Province, Umhlanga; 12 Apr. 2018; population bred at SASRI on *Parthenium hysterophorus*; JHAR00911; ethanol coll. CBGP.

Diagnosis

BODY LENGTH. 1.6–2.0 mm.

COLOUR. Body integument black, rostrum black or dark brown, antennae and tarsi dark brown; vestiture of elytra generally consisting of rounded, grey-brown scales, isodiametric or slightly longer than wide, with a few scattered white scales; white scales concentrated on humeri, on sides and at base of median line near scutellum on prothorax.

HEAD. Rostrum in lateral view downcurved at base and almost straight over the rest of length; slightly longer than head capsule + prothorax.

PROTHORAX. Isodiametric (w/l ratio: 1), sides slightly rounded in basal $\frac{2}{3}$, constricted apically, widest slightly behind middle of length.

ELYTRA. Subparallel in basal two thirds (w/l ratio: 0.70), rounded toward apex in apical third.

LEGS. Femora moderately clavate, unarmed, tibiae straight.

GENITALIA. Body of penis moderately elongate (w/l ratio: 0.43), as long as apodemes, sides straight, subparallel, moderately and regularly curved in lateral view (Fig. 5O).

Life history

Smicronyx lutulentus develops in the seeds of the capsules of *Parthenium hysterophorus* L. (Asteraceae; Dhileepan *et al.* 1996).

Distribution

United States of America (Texas; Anderson 1962); introduced as a biocontrol agent of *Parthenium* in Australia (Dhileepan *et al.* 1996) and in the Republic of South Africa (KwaZulu-Natal Province; Strathie *et al.* 2011).

Smicronyx albosquamosus Wollaston, 1854

Fig. 2G; Table 1

Smicronyx albosquamosus Wollaston, 1854: 345.

Differential diagnosis

In southern Africa, *S. albosquamosus* is closest to *S. fallax*. See differential diagnosis section under this species for distinguishing traits.

Diagnosis

BODY LENGTH. 2.0–2.1 mm.

COLOUR. Body integument black; vestiture of elytra consisting of recumbent, slightly overlapping brown scales, slightly longer than wide, concealing integument, and white scales usually forming a pale oblique band between humeri and apical third of elytral suture.

HEAD. Rostrum moderately downcurved in lateral view, as long as head capsule + prothorax.

PROTHORAX. Slightly wider than long (w/l ratio: 1.15), sides moderately rounded in basal 2/3, constricted in apical 1/3, with spots of whitish scales near humeri and at base near scutellum.

ELYTRA. Subparallel in basal two-thirds (w/l ratio: 0.65), rounded toward apex in apical third.

LEGS. Covered with white and brown scales; femora moderately clavate, armed with small but distinct ventral tooth, tibiae straight; claws unequal in length, at least for fore tarsi.

GENITALIA. Body of penis elongate (w/l ratio: 0.30), 1.2 × as long as apodemes, sides straight, subparallel, converging near apex; curvature moderate in lateral view (Fig. 5H).

Life history

Smicronyx albosquamosus is found across its distribution range on pods and flowers of *Cuscuta* spp. Adults were collected in southern Africa from November to April.

Distribution

This species is widely distributed across Africa and the Mediterranean region. In the Republic of South Africa, this species is only found in subtropical areas (Gauteng, KwaZulu-Natal, Limpopo and Mpumalanga provinces)

Remark

The identity of this species was established by comparisons of specimens with reference material from the Mediterranean region reported by Haran *et al.* (2017).

Smicronyx namibicus Haran, 2018 Figs 2H, 5P; Table 1

Smicronyx namibicus Haran, 2018: 282.

Differential diagnosis

Of the African Smicronychini, *Smicronyx namibicus* can be distinguished by the scales on elytra forming a contrasting black square on basal half of interstriae 1–4, surrounded with white scales (Haran 2018).

Material examined

REPUBLIC OF SOUTH AFRICA • 1 ♂; Kwazulu-Natal Province, Escourt; 4 Jan. 1899; G.A.K. Marshall leg.; BMNH.

Other material (holotype)

See Haran (2018).

Diagnosis

BODY LENGTH. 2.0–3.0 mm.

COLOUR. Body integument black, antennae, femora and tibiae dark reddish; vestiture of elytra generally consisting of recumbent, rounded or slightly longer than wide scales, forming a dark-brown square in basal half and between interstriae 5 of each elytron; rest of scales on elytra greyish to brown, paler near dark-brown square; vestiture of prothorax consisting of brownish scales, with 5 longitudinal whitish stripes.

HEAD. Rostrum slightly longer than head capsule + prothorax in lateral view, moderately downcurved, curvature stronger near base and near antennal insertion.

PROTHORAX. Slightly wider than long (w/l ratio: 1.06), widest before middle of length, sides greatly rounded in basal $\frac{2}{3}$.

ELYTRA. Distinctly rounded, widest before middle of length (w/l ratio: 0.79).

LEGS. Femora moderately clavate, armed with a distinct ventral tooth, tibiae straight.

GENITALIA. Body of penis elongate (w/l ratio: 0.47), $0.8 \times$ as long as apodemes, sides straight, subparallel, apex truncate, moderately and regularly curved in lateral view (Fig. 5P).

Life history

Unknown. The adults were collected in December in the Republic of South Africa and in November in Tanzania.

Distribution

Tanzania (Island of Zanzibar, Haran 2018), Republic of South Africa (Kwazulu-Natal Province).

Remarks

Smicronyx namibicus was wrongly described from Namibia due to a misinterpretation of the handwritten label of the holotype. The locality of this specimen is ‘Zanzib’ (Island of Zanzibar, Tanzania) and not ‘Namib’ (Namib Desert) as reported in Haran (2018). I thank Helene Perrin (MNHN) for highlighting this misreading.

Key to *Smicronychini* of southern Africa

1. Vestiture of elytra consisting of imbricate scales, polygonal, shiny, completely concealing the integument; middle of 4th interstria generally with a band of white scales (Fig. 1A). Body of penis very elongate (ratio w/l: 0.15), bearing erect setae laterally (Fig. 5A) *Sharpia madibai* sp. nov.
– Vestiture of elytra different, not combining these traits, lacking contrasting band of white scales on 4th interstria. Body of penis shorter (ratio w/l above 0.20), sides smooth, not bearing erect setae .. 2
2. Protibiae with a distinct tooth or thickening near middle of ventral side. Body size generally over 2.5 mm 3 (genus *Afrosmicronyx* Hustache, 1935)
– Ventral side of protibiae straight or slightly bisinuate, lacking tooth or thickening near middle of length. Body size equal to or under 2.5 mm 6 (genus *Smicronyx* Schönherr, 1843)
3. Body black; scales black, short, not overlapping on elytra (Fig. 1B) *A. cyenii* sp. nov.
– Body covered with grey or brown or whitish scales, overlapping on elytra and concealing the integument 4
4. Antennae slender, segments 3–4 of funicle longer than wide. Tarsi elongate, the length of article 4 exceeding 3, as long as the length of 1 + 2 *A. nebulosipennis* sp. nov.
– Antennae more robust, segment 3–4 of funicle wider than long. Tarsi shorter, length of article 4 exceeding 3, shorter than the length of 1 + 2 5
5. Sides of body of penis straight (Fig. 5C), length longer (ratio w/l: 0.36) *A. louwi* sp. nov.
– Sides of body of penis convex (Fig. 5D), length short (ratio w/l: 0.56) *A. marshalli* sp. nov.
6. Integument dark red or with some shade of reddish. Vestiture of elytra forming a large transverse white band on apical half (Fig. 2E); scales rounded, as long as wide. Rostrum very distinctly downcurved in lateral view *S. zonatus* Haran, 2018
– Integument of elytra of mature specimens at least partly black. Vestiture forming multiple, poorly-defined and narrow transverse whitish stripes, or vestiture homogenous or almost glabrous. Rostrum moderately downcurved in lateral view (Fig. 3D–E) 7
7. Body size over 2.2 mm 8
– Body size under 2.2 mm 9

8. Integument of prothorax smooth. Scales on elytra elliptical, not overlapping ...*S. gracilipes* sp. nov.
 – Integument of prothorax densely granulate. Scales on elytra rounded, isodiametric, overlapping
 *S. similis* sp. nov.
9. Body of penis very short, isodiametric or slightly longer than wide in dorsal view (ratio w/l: 0.8–1), the sclerotized part of dorsal face narrowed longitudinally (Fig. 5L–M). Mesanepisterna and Metanepisterna densely covered with overlapping, rounded, whitish scales. 10
 – Body of penis distinctly longer than wide (ratio w/l < 0.6), dorsal face fully sclerotized (Fig. 5G–K, N–P). Episterna with brown or grey scales, generally not concealing the integument. 11
10. Prothorax strongly granulate, isodiametric (ratio w/l: 1). Elytra with white and brown scales forming ill-defined transverse white bands (Fig. 2A–C). Body of penis very short (ratio w/l: 1; Fig. 5L) *S. san* sp. nov.
 – Prothorax with coarse punctures, slightly longer than wide (ratio w/l: 1.07). Elytra with homogeneous cover of greyish scales, not forming particular pattern (Fig. 2D). Body of penis more elongate (ratio w/l: 0.60; Fig. 5M) *S. drakensbergensis* sp. nov.
11. Scales on elytra of fresh specimens scarce, leaving large glabrous areas (Fig. 1H–I) 12
 – Scales on elytra of fresh specimens forming a more or less dense cover over dorsal surface (Figs 1J–L, 2F–H) 13
12. Body of penis black, elongate (ratio w/l: 0.28; Fig. 5G), apodemes $\frac{1}{4}$ the length of the body. White scales on elytra generally forming transverse bands (Fig. 1H) *S. pseudococcus* sp. nov.
 – Body of penis brown, less elongate (ratio w/l: 0.44; Fig. 5H), apodemes as long as length of body. White scales on elytra very scarce, forming elliptical spots (Fig. 1I) *S. paucisquamis* sp. nov.
13. Scales on elytra forming a contrasting black square on basal half of interstriae 1–4, surrounded with white scales (Fig. 2H) *S. namibicus* Haran, 2018
 – Pattern of elytra different 14
14. Pale scales on elytra generally condensed in an oblique band between shoulders and apical $\frac{2}{3}$ of suture of elytra (Figs 1J, 2G). Body of penis elongate (ratio w/l < 0.35) 15
 – Pale scales on elytra forming multiple ill-defined transverse stripes or only condensed on shoulders. Body of penis shorter (ratio w/l > 0.40) 16
15. Prothorax isodiametric (ratio w/l: 1). Claws always equal in length. Body of penis parallel sided in dorsal view, regularly thick in lateral view (Fig. 5I) *S. fallax* (Gyllenhal, 1836)
 – Prothorax slightly wider than long (ratio w/l: 1.15). Claws generally unequal in length. Sides of body of penis slightly expanding toward apex in dorsal view*S. albosquamosus* Wollaston, 1854
16. Scales on elytra rounded, homogeneously brown with white scales condensed on shoulders and a few scattered on the rest of elytra (Fig. 2F). On *Parthenium* L. sp.*S. lutulentus* Dietz, 1894
 – Scales on elytra elongate, much longer than wide, brown, grey or white, the pale scales forming ill-defined transverse bands (Fig. 1K–L) 17
17. Integument of elytra at least partly reddish (Fig. 1L). Endophallus slightly sclerified, not visible at base of body of penis in dorsal view*S. pauperculus* Wollaston, 1864
 – Integument of elytra entirely black (Fig. 1K). Endophallus sclerified, forming elongated striae at base of body of penis in dorsal view*S. australis* sp. nov.

Discussion

This study enabled the recognition of 18 species of Smicronychini in southern Africa, of which 12 are described as new. The genera *Sharpia* and *Afrosmicronyx* are reported for the first time from this area. Southern African Smicronychini contain some typical tropical African elements (Genus *Afrosmicronyx*; species allied to *Smicronyx guineanus*) in its northern and central parts (northeastern South Africa, Zimbabwe). It also includes some widely distributed elements across the whole of Africa and the Mediterranean area (*S. albosquamosus*, *S. pauperculus*). Several species endemic to southern Africa are morphologically and molecularly closely related to West Palearctic species: *S. jungermanniae* and *S. fallax*; *S. pauperculus* and *S. australis* sp. nov.; *S. coecus* and *S. pseudocoecus* sp. nov. These pairs of species suggest a somewhat recent contact zone and then an allopatric speciation between these regions, as has been shown in several groups of organisms, including in plants and weevils (Hernández-Vera *et al.* 2013; Pirie *et al.* 2016).

The plant associations reported in this study are consistent with the known host families of Smicronychini in the old world: Gentianaceae, Convolvulaceae and Orobanchaceae (Caldara *et al.* 2014; Dieckmann 1990). However, the following genera are newly reported: *Cychnium* (Orobanchaceae), *Chironia*, *Orphium* and *Sebaea* (Gentianaceae). Several species of *Smicronyx* were found on the introduced dodder *Cuscuta campestris* and can be considered as candidate species for its biocontrol. Apart from this species, most *Cuscuta* of southern Africa are rare and red-listed species that do not threaten crops.

Acknowledgments

I wish to thank Robert Anderson (CMNC), Max Barclay (BMNH), Johannes Bergsten (NHRS), Roman Borovec (FFWS), Lourdes Chamorro (NMNH), Enzo Colonnelli, Roberto Casalini (MCZ), Madougou Garba (DGPVN, Niger), Elizabeth Grobbelaar, Riaan Stals (SANC), Ruth Müller (TMSA), Hélène Perrin (MNHN) and Simon van Noort (SAMC) for providing access to collections and for the loan of specimens that made this study possible. I thank Stuart Hall (Stellenbosch Botanical Garden, Republic of South Africa) for his help with the location and identification of plant associations for *Smicronyx*. I also thank Paula Strauss, Gary Beukman and Michael Lutzeyer for access to the Grootbos Private Nature Reserve and their friendly assistance during sampling and Laure Benoit (CIRAD) who assisted with the production of Barcode sequences. The following services are acknowledged for providing permits for insect sampling: Western Cape Province (Western Cape Nature Conservation Board [permit No. CN44-30-4229] and the Cape Research Centre [Republic of South African National Parks, CRC/2019-2020/012--2012/V1]); KwaZulu-Natal Province (Ezemvelo KZN Wildlife permits office, Collecting Permit KZN: OP1382-2019); Namibia (Collecting and MET delivered by Gobabeb in the course of the International Diptera Conference IDC9-2018). Finally, I acknowledge the collections platform of the CBGP (Emmanuelle Artige) for access to collections and imaging systems and Peter Biggins (CIRAD) who reviewed the English.
