**Abstract.** The genus *Trypheridium* Brancucci, 1985 is endemic to the Hindu Kush Himalayan Region, and is currently known from a single species, *T. nuristanicum* (Wittmer, 1956). Here, the genus is reviewed, *T. nuristanicum* nom. emend. is re-described and *T. kashmiricum* sp. nov. is described from Kashmir Himalayan Region of India. Descriptions, diagnoses, high quality images, distribution maps and identification keys are presented. The morphology and distribution of *Trypheridium* are discussed and compared with those of the closely related genus *Trypherus* LeConte, 1851.

**Keywords.** Ichthyurini, Himalaya, Kashmir, morphology, taxonomy.

Zubair R.M., Maqbool A., Wachkoo A.A. & Biffi G. 2021. A review of the Himalayan genus *Trypheridium* Brancucci (Coleoptera: Cantharidae: Chauliognathinae) with description of a new species. *European Journal of Taxonomy* 764: 18–36. <https://doi.org/10.5852/ejt.2021.764.1467>

**Introduction**

The genus *Trypheridium* Brancucci, 1985 was originally described from the Hindu Kush Himalayan Region, for a single species *Trypherus nuristanicus* Wittmer, 1956 based on distinct morphological characters and disjunct distribution. Superficially, *Trypheridium* resembles *Trypherus* LeConte, 1851 but can be distinguished from the latter by ‘aberrant’ sexual characters and unmodified mid legs (Brancucci 1985a).

*Trypheridium* seems to be restricted to the Hindu Kush Himalayan Region whereas *Trypherus* is widespread across the eastern Palaearctic and the Nearctic, with a greater diversity in Taiwan (Brancucci 1985b; Pelletier & Hébert 2014; Satô *et al.* 2014). The Hindu Kush is an 800 km long mountain range that stretches through Afghanistan, from its centre to Northern Pakistan and into Tajikistan, and is home to four global biodiversity hotspots, and hundreds of mountain peaks over 6000 m (Chettri *et al.* 2008; Searle 2013). The range forms the western section of the Hindu Kush Himalayan Region and is the westernmost extension of the Pamir Mountains, the Karakoram and the Himalayas.

In this study we revise the taxonomy of the genus *Trypheridium* and describe a new species *T. kashmiricum* sp. nov. from the Kashmir Himalayan Region of India and re-describe *T. nuristanicum* nom. emend. All descriptions include diagnoses, taxonomic discussions, and high quality stacked images. In addition, we provide an illustrated identification key to species, as well as maps showing the known distribution ranges.

## Material and methods

Specimens of *T. kashmiricum* sp. nov. were collected at Waripora, Tangmarg area (34°05'30" N, 74°33'31" E, 1639 m a.s.l.) of Baramulla District, in Kashmir Valley, the Palaearctic portion of India, located in the northwestern part of the Indian subcontinent between 33°22' and 34°50' N latitudes and 73°55' and 73°33' E longitudes (Maqbool *et al.* 2018; Wachkoo *et al.* 2018). The specimens were hand collected from the leaves of walnut trees (*Juglans regia* L.), which were heavily infested with aphids (Fig. 1). The alcohol (70% ethanol) preserved specimens were air dried and card mounted for taxonomic studies.

The map of the sampling site was created by using the administrative-boundary vector map of India at district level (Survey of India) at a scale of 1:1 000 000. Geographical coordinates of the sampling

**Fig. 1.** *Trypheridium kashmiricum* sp. nov., ♀. **A.** Habitat (*Juglans regia* L.). **B.** On a walnut leaf.

site were imported to mapping software and the sampling site was plotted. The ArcMap module of the ArcGIS package ver. 10.1 ([www.esri.com](http://www.esri.com)) was used to prepare the map of Kashmir Valley showing the sampling site. The species distribution map was prepared using Google maps.

The specimens were observed under a Magnus MS 24 stereoscopic binocular microscope. Card point mounted specimens were placed inside a light-box using cool daylight LED lamps (3W) and images were captured using a DSLR camera (Nikon D5300) with a macro lens (Tokina 100 mm f2.8). Multiple images were generated using an auto stacking-rail (Stackrail rs90) and merged using Combine ZP software. The final images were cleaned with Adobe Photoshop CS4. The abdomens of specimens were detached with forceps and treated with 20–30% KOH for about 48 hours. After appropriate transparency was achieved, abdomens were cleaned in 75% ethanol and placed on cavity slides with glycerin. Abdominal sternites and genitalia were dissected and mounted for microphotography. For brightfield microscopy, prepared slides were placed on a stage prepared from cardboard and provided with an LED lamp (3W) to produce the transmission light beam. For darkfield microscopy a darkfield illumination filter was used to illuminate unstained specimens. Microphotographs were captured with a digital mirrorless camera (Nikon Z50) attached with infinity-corrected microscope objectives (Lomo 3.7 × and Nikon CFI Plan Achromat 10X).

The terminology used in the descriptions follows that of Brancucci (1980, 1985b), except for the tergite IX and X that replaces the terms paraproct and proctiger respectively, and a new orientation of the aedeagus. The correct orientation of the aedeagus of the Chauliognathinae is still contentious, as two opposite terminologies are used for each of the lineages (cf. Biffi 2020). Brancucci (1985b) attempted to correct the general hypothesis of homology for the aedeagus of the Chauliognathinae proposed by Magis & Wittmer (1974). However, the terminology used by Brancucci (1985a, 1985b) is actually based on an aedeagus disposed in a dorsal position, rather than ventral as he stated. We therefore consider the aedeagus of species of *Trypheridium* as having two elongate outgrowths: right paramere (rather than “left paramere” sensu Brancucci), and a prolongation of the tegmen to the left (rather than “right prolongation of tegmen” sensu Brancucci). The left paramere (“right paramere” sensu Brancucci) is here considered to be missing. The descriptions and diagnoses below were adapted to accordingly follow this present orientation of the aedeagus.

Figs 2–7

*Trypheridium* Brancucci, 1985a: 245.

*Trypheridium* – Kazantsev 2004: 30 (catalogue); 2012: 403 (catalogue). — Kazantsev & Brancucci 2007: 297 (catalogue).

### Type species

*Trypherus nuristanicus* Wittmer, 1956, by original designation.

### Diagnosis

*Trypheridium* is similar to *Trypherus*, and distinguished by sexual characters: tergite IX with dorsal and ventral blades (“lames tergaes et sternales”) very long and asymmetrical (Figs 3A–D, 6E–F); aedeagus without left paramere, median lobe membranous (Figs 3F–J, 6G–I), with orifice apically (not pre-apically as in *Trypherus*); female with sternite VII remarkably broad, partly or completely concealing most of sternite VIII (Figs 4G–H, 7B); bursa copulatrix elongate, with two tubular spermathecae and one accessory gland connecting the bursa in its postero-dorsal part (Figs 5F, 7D).

### Re-description (Figs 6–7)

#### Coloration

General coloration pale to sulphur yellow with dark brown to black patches; head yellow anteriorly at frons and clypeus and infusate at vertex and occipital region; antennae dark brown to black, the three or four basal antennomeres yellow; pronotum with a transversal black band at posterior half; elytra with dark brown to black triangular patches, from the base of elytra (not reaching the humeri) and extending posteriorly; wings dark brown; legs dark brown or black, usually fore and mid legs light brown with dark spots; abdominal tergites and ventrites black in the centre and yellow at the margins. Coloration in females usually darker.

#### Male

HABITUS. Length 6.5–8.5 mm.

HEAD. Head (including the eyes) wider than pronotum; vertex flat, frons concave between the eyes, occipital region convex, sides rounded and regularly narrowing behind the eyes. Eyes large, oblong, bulging, longer than wide, broadly separated. Fronto-clypeal suture distinct laterally, indistinct in the middle; anterior margin of clypeus slightly sinuous, nearly straight; labrum membranous. Mandibles arcuate, apex acute, blunt, retinaculum in the same plan as incisor, apex rounded, with a small supplementary tooth at the base of retinaculum. Maxillary palp with fourth palpomere elongate, narrowing apicad. Antennae not juxtaposed, separated by at least the width of antennal sockets; with 11 antennomeres, filiform, without modifications; antennomere I slender, without swellings.

PRONOTUM. Transverse, wider than long, convex; anterior margin broadly arched, lateral margins nearly straight, slightly narrowing posteriorly; posterior margin projected posteriorly; anterior and posterior angles rounded, barely distinct. Elytra short, 1.2–1.4 times longer than combined width, slightly narrowed laterally, suture dehiscent posteriorly, apex rounded.

WINGS. With reduced venation, radial cell  $2R_1$  closed; vein r-m barely visible, vein Cu straight, vein Mr fading; transversal vein cu-a absent;  $R_r$  extends beyond the joining of vein r; vein  $A_{x_2}$  well visible, not joining  $A_{x_{1+2}}$  and ending near the joining of vein A and  $A_{x_{1+2}}$ .

LEGS. Slender, without swellings, teeth or remarkable modifications; apex of fore tibia with a pair of tiny spurs; all tarsal claws with broad internal teeth.

ABDOMEN. Weakly sclerotised; tergites with a pair of small glandular pores on the distal corners; pores of tergite VIII in the apex of projections. Tergite VIII long and broad, with distal corners projected posteriorly, distal margin arcuate, concave. Tergite IX (paraproct) strongly modified in a capsule with a pair of long and asymmetrical lamellar projections directed ventrally; left blade (“lame sternale” of

Brancucci) longer, flattened; right blade (“lame tergale” of Brancucci) shorter, more strongly curved ventrally. Tergite X (proctiger) divided posteriorly into two projecting lobes. Sternite VIII (ventrite VII) asymmetrical, distal margin sinuous and deeply notched, sides projected posteriorly. Sternite IX concealed underneath sternite VIII, elongate, lamellar, weakly sclerotised.

**AEDEAGUS.** Elongated and weakly sclerotised; left paramere absent, right paramere and the prolongation of tegmen elongate and directed posteriorly; left prolongation of tegmen broad and lamellar, margins sinuous. Median lobe membranous, short, not twisted, with its broad opening located apically.

### **Female**

Similar to males, except for eyes slightly smaller and more separated; sternite VII long and broad, mostly concealing sternite VIII, distal margin with elongate lobes projecting posteriorly. Sternite VIII membranous, broadly rounded, distal margin with a broad rounded lobe projecting posteriorly; coxites small, not fused medially, anterior arms very long and slender, apparently fused with valvifers, styles elongate, digitiform. Genitalia membranous, consisting of a long and broad vagina; oviduct anteriorly in the vagina; bursa copulatrix elongate, wrinkled, spiralling; spermatheca formed by two tubular projections; accessory gland large, connected by a long winding duct to the postero-dorsal part of bursa copulatrix.

### **Distribution**

*Trypheridium* seems to be endemic to the Hindu Kush Himalayan Region. The only species described prior to this work has been reported from Tajikistan, Afghanistan (Nuristan) and Pakistan (Fig. 8A). Herein, we report a new species of this genus from India (Fig. 8B).

### **Key to the species of *Trypheridium* Brancucci, 1985**

1. Males: right blade of tergite IX bifurcating terminally into two unequal lobes (Fig. 3A–D); tergite X divided into two very long asymmetrical projections (Fig. 3B). Females: sternite VII long, mostly concealing sternite VIII, projecting beyond the tip of abdomen, distal margin with three projections (Fig. 4G–H).....*Trypheridium kashmiricum* sp. nov.
- Males: right blade of tergite IX undivided (Fig. 6E–F); tergite X divided into two short asymmetrical lobes (Fig. 6D, F). Females: sternite VII shorter, partly exposing sternite VIII, distal margin with two projections (Fig. 7B–C) .....*Trypheridium nuristanicum* (Wittmer, 1956)

### *Trypheridium kashmiricum* sp. nov.

urn:lsid:zoobank.org:act:DF4DAB14-589A-4B50-A37C-9EFC31438D86

Figs 2–5

### **Diagnosis**

This species resembles *T. nuristanicum* in general morphology and coloration, but differs in the structure of male and female terminal abdominal segments. In males, the right blade of tergite IX bifurcates terminally into two unequal lobes and tergite X divides into two very long asymmetrical projections. Sternite VII in females projects beyond the tip of abdomen, mostly concealing sternite VIII, and forms three projections apically.

### **Etymology**

The species epithet is in reference to the type locality.

INDIA • ♂; Jammu and Kashmir, Baramulla, Tangmarg; 34°05'30" N, 74°33'31" E; 1639 m a.s.l.; 10 Aug. 2018; Zubair R.M. leg.; KUIC 0013.

### Paratypes

INDIA • 1 ♂, 2 ♀♀; same collection data as for holotype; KUIC 0014 to KUIC 0016.

## Other material

INDIA • 1 ♂; Jammu and Kashmir, Baramulla, Tangmarg; 34°05'30" N, 74°33'31" E; 1639 m a.s.l.; 10 Aug. 2018; Zubair R.M. leg.; KUIC 0017.

## Description

### Coloration

Head black in vertex and occipital region, yellow in frons and clypeus. Antennae dark brown, except the three and part of fourth basal antennomeres and sometimes underside of latter, yellow; sometimes antennomeres II and III infusate. Mandibles yellowish with dark-brown apex. Palpi light brown, infusate at distal palpomeres. Pronotum partly translucent, yellow with transversal black band at posterior half, not reaching lateral and posterior pronotal margins. Elytra sulphur yellow with triangular dark brown patch from base of elytra extending posteriorly along suture up to about posterior third of elytra; integument shining, covered with fine yellow pubescence. Wings, meso- and metaventrite dark brown to black. Legs: fore and mid coxae yellow, hind coxa partly yellow and partly brown; fore and mid femora yellowish (black in females) except having black patch towards dorsal apex; fore tibia and tarsus yellow; mid tibia testaceous brown and tarsus dark brown; hind legs completely dark brown except yellowish brown basal margin; darker specimens have legs more broadly infusate. Abdominal ventrites and tergites dark brown to black at the centre and yellow at margins; last ventrites and tergites light to dark brown (especially in females).

### Male (Figs 2–3)

HABITUS. Length 7.8 mm in holotype (Fig. 2A–C), 7.6 mm in paratype.

HEAD. Head (including eyes) wider than pronotum (Fig. 2D–E), 1.3 times as wide as long (across middle of eyes); vertex flat, frons slightly concave between eyes, with pair of longitudinal furrows running between antennae sockets; area around antennal sockets depressed and with carinated margin, forming ridge between antennae that reaches up to vertex; integument smooth and lustrous, with very small punctures and densely covered with short and fine setae. Fronto-clypeal suture defined laterally, indistinct medially. Eyes large, bulging, longer than wide, glabrous; interocular space 1.6 times wider than widest width of eye. Antennae filiform (Fig. 2F), slender, 0.56 times body length, covered with short and fine setae; antennomere I 1.68 times length of II, 0.88 times length of antennomere III, 0.84 times length of antennomere IV, antennomeres IV–VI longest, subequal, latter decreasing apicad, XI pointed at apex.

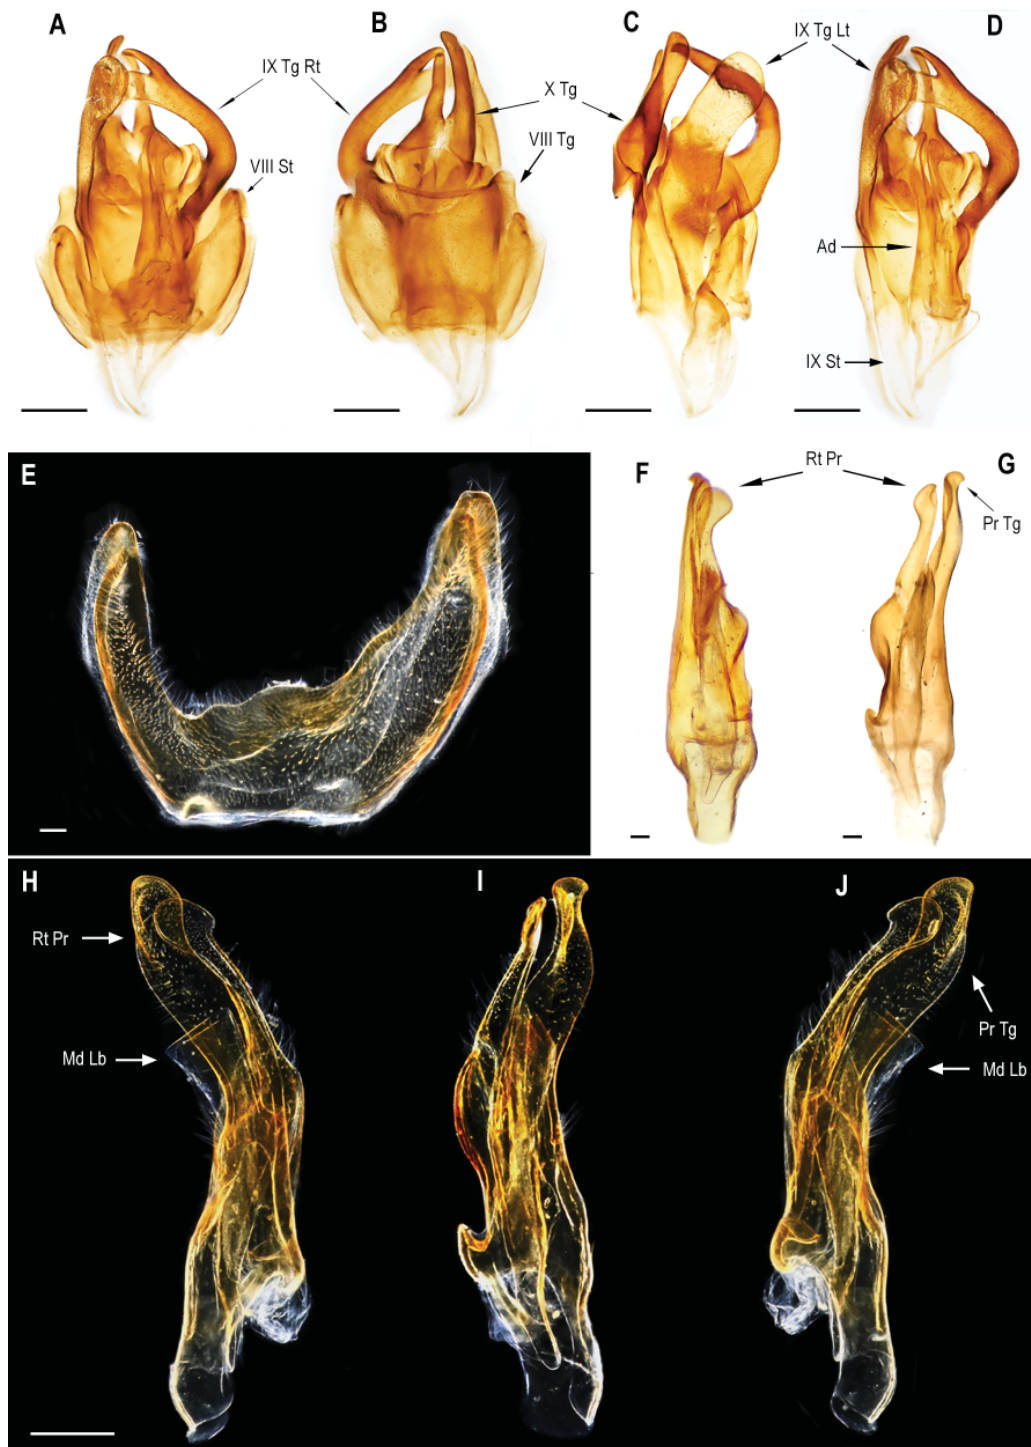

PRONOTUM. Transverse (Fig. 2G) 1.3 times as wide as long, sides narrowed posteriorly, rounded, anterior margin arcuate, anterior angles rounded, not defined, posterior margin projected posteriorly, sinuous; disc slightly arched, integument partly translucent, smooth and lustrous, coarsely punctured and densely covered with fine pubescence. Scutellum with sides parallel, apex truncate. Scutellum trapezoidal, with pair of shallow and broad concavities anteriorly, posterior margin with rounded notch.

ELYTRA. Short, 0.28 times as long as body length, about 1.89 times length of pronotum, 1.2 times longer than width of both elytra; sides slightly narrowed at posterior third, sutures parallel anteriorly and

**Fig. 2.** *Trypheridium kashmiricum* sp. nov. ♂, holotype (KUIC 0013). **A.** Habitus, dorsal view. **B.** Habitus, lateral view. **C.** Habitus, ventral view. **D.** Head, frontal view. **E.** Head, lateral view. **F.** Antenna. **G.** Pronotum. **H.** Hind wing. **I.** Apex of fore tibia showing a pair of tiny spurs. **J.** Terminal segments, ventral view. Scale bars: A–D, H–J=0.5 mm; E–G=0.1 mm.

dehiscent from posterior half, apex of each elytron rounded and flattened; integument slightly rugose, almost smooth, with fine punctures and densely covered with short and fine setae.

WINGS. With reduced venation (Fig. 2H), radial cell  $2R_1$  closed; vein r-m barely visible, vein Cu straight; transversal vein cu-a absent; Rr extends beyond the joining of vein r; vein  $A_{x2}$  well visible, not joining  $A_{x1+2}$  and ending near the joining of vein A and  $A_{x1+2}$ .

LEGS. Slender, increasing in length from fore to hind, without strong modifications. Apex of fore tibia with a pair of very tiny spurs (Fig. 2I).

ABDOMEN. Weakly sclerotised; tergite VIII globose, longer and wider than preceding ones, distal margin arcuate, concave, posterior angles projected, with conspicuous glandular openings; tergite IX with two elongated, asymmetrical and protruding lamellae (blades) that converge towards the apex, giving it a shape of ‘forceps’ (Fig. 2J); right blade curves ventrally and bifurcates terminally into two unequal lobes (Fig. 3A); left blade broad, apex rounded (Fig. 3C), less sclerotised, almost parallel to abdominal axis; dorsally, tergite IX with pair of glandular openings in apex of short projections, lateral margins rounded, posterior margin slightly arcuate; tergite X large and produced into two unequal, asymmetrical, narrow and elongated lobes (Fig. 3B–C). Sternite VIII wider than long, ‘U’ shaped, asymmetrical, forming two narrow and very long asymmetrical lobes (Fig. 3E), sternite IX internalised, weakly sclerotised, elongate, flanking the aedeagus laterally to left inside abdomen.

AEDEAGUS. Elongated and weakly sclerotised (Fig. 3F–G); left paramere absent, right paramere and prolongation of tegmen directed posteriorly. Right paramere elongated (Fig. 3H), ventral face with row of setae, apex flattened, forming rounded lobe; left prolongation of tegmen broad and lamellar (Fig. 3J), margins sinuous, apex rounded with tip pointing laterally. Median lobe membranous, short, not twisted, with its broad opening located apically.

#### **Female** (Fig. 4–5)

HABITUS. Length 7.4–7.6 mm (n=2) (Fig. 4A–C).

Similar to male, except for eyes slightly smaller (Fig. 4D–E), interocular distance across base of antennae 1.16 times wider than in male; elytra 0.32 times body length, 1.88 times the pronotum length; sternite VII variable (Fig. 4G–H), long and projecting posteriorly into 3 flattened lobes: 2 shorter pointed lobes laterally and medial lobe broad, parallel-sided, distal margin, with rounded notch (Fig. 5A); sometimes lateral lobes longer, almost as long as medial lobe, and distal margin of medial lobe truncate, not notched. Sternite VIII (Fig. 5C) almost completely concealed by sternite VII, membranous, broadly rounded, distal margin with broad rounded lobe projecting posteriorly; tergite VIII rounded on sides basally with wide and deep notch apically forming two apical lobes; coxites small (Fig. 5E), not fused medially, anterior arms very long and slender, apparently fused with valvifers, styles elongate, digitiform. Genitalia membranous (Fig. 5F); vagina long and broad; bursa copulatrix elongate, wrinkled, spiralling; spermatheca formed by two tubular projections; accessory gland large, connected by long winding duct to the postero-dorsal part of bursa copulatrix.

#### **Biological notes**

The specimens were collected on walnut tree leaves (*Juglans regia* L.) infested with walnut aphids, *Chromaphis juglandicola* (Kaltenbach, 1843) and *Panaphis juglandis* (Goeze, 1778).

#### **Distribution**

India (Baramulla, Kashmir) (Fig. 8A–B).

*Trypheridium nuristanicum* – Brancucci 1985a: 246, figs 1–4 (re-description); 1985b: 296 (species list). — Kazantsev 2004: 30 (catalogue); 2012: 403 (catalogue). — Kazantsev & Brancucci 2007: 297 (catalogue).

### Diagnosis

*Trypheridium nuristanicum* differs from *T. kashmiricum* sp. nov. in the structure of the male and female terminal abdominal segments. In males, the right blade of tergite IX is undivided terminally and tergite X is divided into two short asymmetrical lobes. Sternite VII in females is short, partly exposing sternite VIII, with 2 projections at the distal margin.

### Re-description (partly adapted from Wittmer 1956 and Brancucci 1985a)

#### Coloration

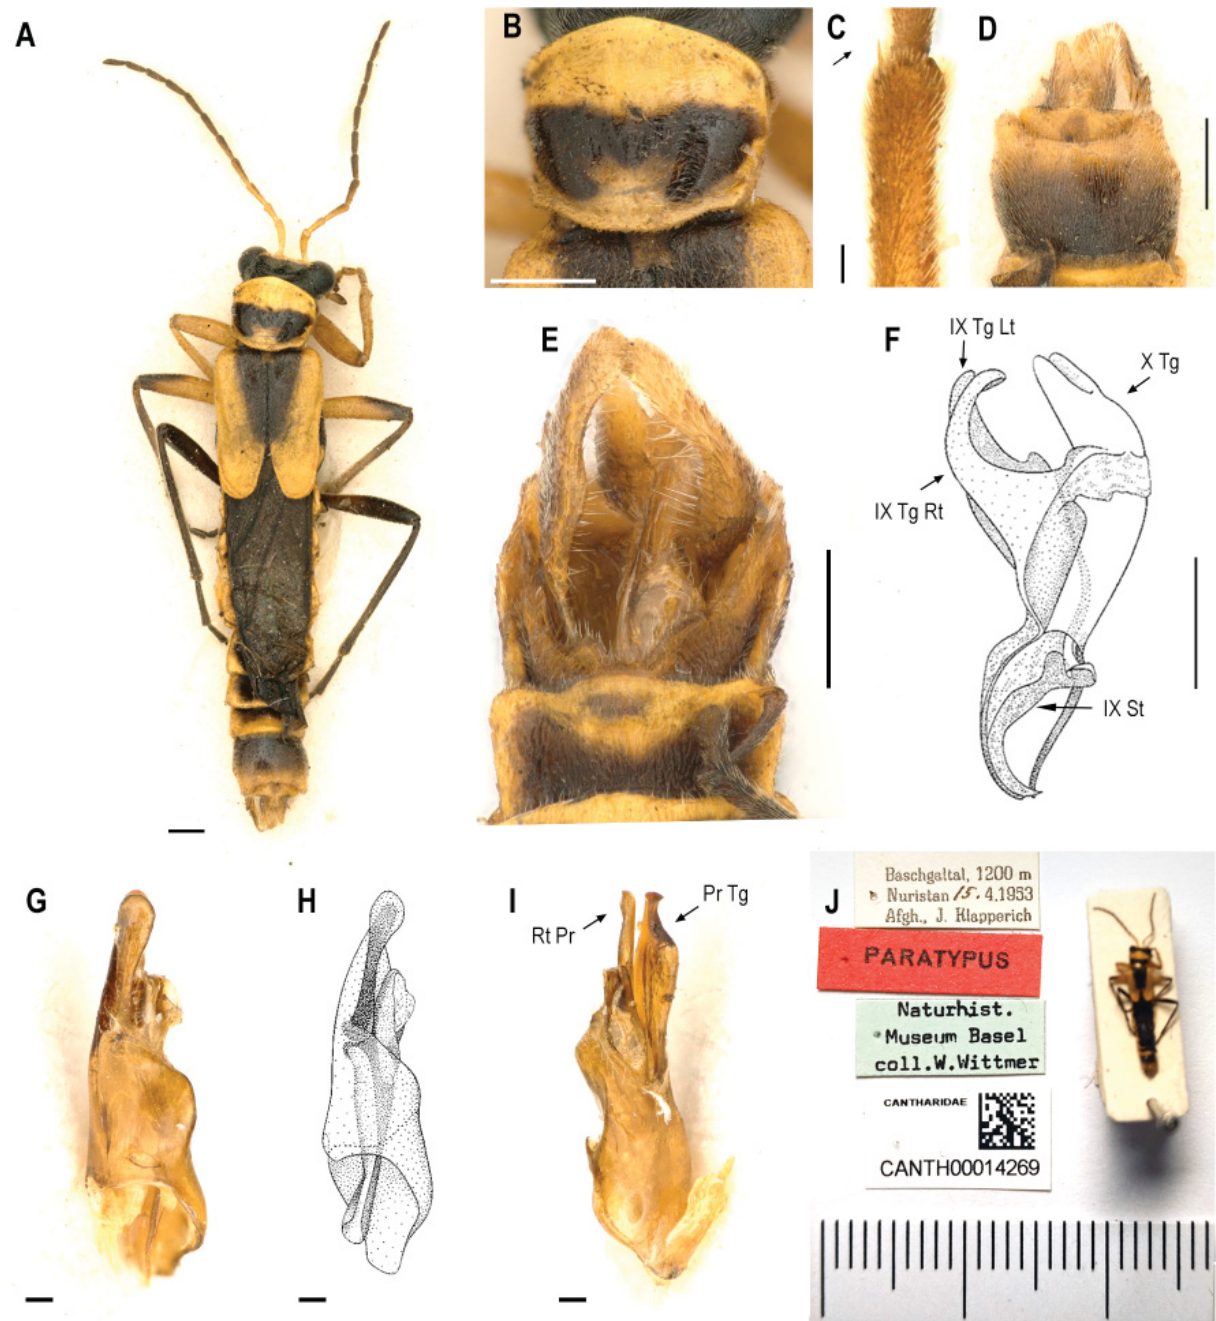

Head black in the vertex and occipital region, yellow in the frons and clypeus. Antennae dark brown, except the three or four first antennomeres and sometimes the underside of the later, yellow. Palpi light brown, infuscate at distal palpomeres. Pronotum yellow with a transversal black band at posterior half, nearly reaching the lateral and posterior pronotal margins. Elytra sulphur yellow, sometimes lighter at the apex; a triangular dark brown patch from the base of elytra extending posteriorly along the suture up to about posterior third of elytra. Wings, meso- and metaventrite dark brown to black. Legs usually black; fore tibia and base of femur sometimes testaceous to light brown, fore femur rarely completely testaceous; bases of mid femur and tibia sometimes lighter. Abdominal ventrites and tergites dark brown to black at the centre and yellow at the margins; last ventrites and tergites mostly to completely yellow. Coloration in females, especially of the legs, usually a little darker.

#### Male (Fig. 6)

HABITUS. Length 6.5–8.5 mm (Fig. 6A).

HEAD. Head (including the eyes) wider than pronotum; vertex flat, frons slightly concave between eyes, with fine longitudinal furrow in middle, which ends in semicircular impression between antennae sockets; integument smooth and lustrous, with very small punctures and densely covered with short and fine setae. Eyes large, bulging; interocular space slightly wider than widest width of eye. Antennae filiform, slender, reaching apex of elytra posteriorly, covered with short and fine setae; antennomere I slender, II more than a third shorter than III, antennomeres IV and V subequal and following decreasing in length.

PRONOTUM. Transverse (Fig. 6B) 1.1 times as wide as long, sides narrowed posteriorly, anterior margin regularly arched, anterior angles barely defined, posterior margin projected posteriorly, truncate at middle and concave laterally; disc slightly arched, integument smooth and lustrous, coarsely punctured and densely covered with fine pubescence. Scutellum with sides parallel, apex truncate.

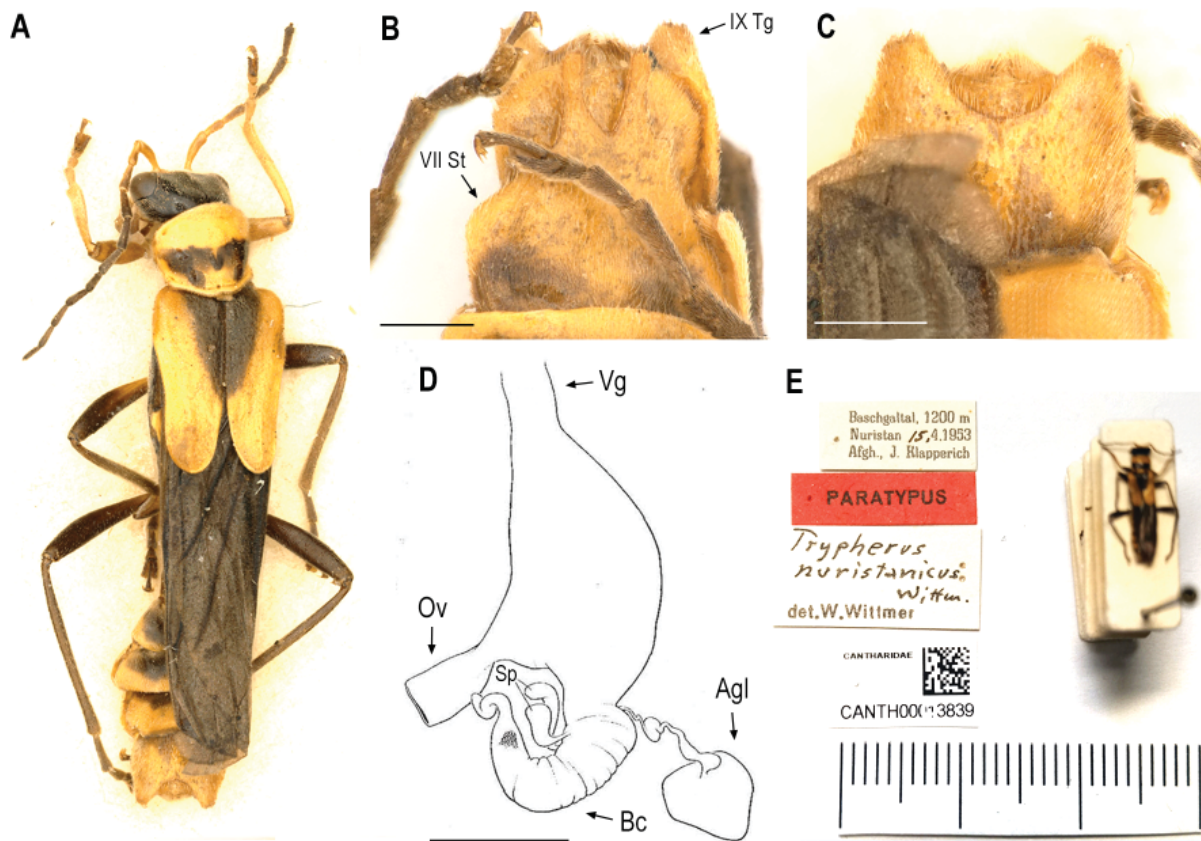

**Fig. 6.** *Trypheridium nuristanicum* (Wittmer, 1956) nom. emend., paratype, ♂ (CANTH00014269, NHMB). **A.** Dorsal habitus. **B.** Pronotum. **C.** Apex of fore tibia showing a pair of tiny spurs (arrow). **D.** Terminal segments, dorsal view. **E.** Terminal segments, ventral view. **F.** Terminal segments, lateral view. **G–H.** Aedeagus, lateral view. **I.** Aedeagus, ventral view. **J.** Paratype label. Abbreviations: IX St=sternite IX; IX Tg Lt=left blade of tergite IX; IX Tg Rt=right blade of tergite IX; X Tg=Tergite X; Pr Tg=prolongation of tegmen; Rt Pr=right paramere. Scale bars: A–B, D–F=0.5 mm; C, G–I=0.1 mm. Line drawings (F, H) adapted from Magis & Wittmer (1974).

**ELYTRA.** Short, 1.4 times longer than width of both elytra; sides slightly narrowed at posterior third, sutures parallel anteriorly and dehiscent from posterior third, apex of each elytron rounded and flattened; integument slightly rugose, almost smooth, with fine punctures and densely covered with short and fine setae.

**LEGS.** Slender, increasing in length from fore to hind, without strong modifications. Apex of fore tibia with pair of tiny spurs (Fig. 6C).

**ABDOMEN.** Weakly sclerotised; tergite VIII globose (Fig. 6D), longer and wider than preceding ones, distal margin arcuate, concave, posterior angles with conspicuous glandular openings; tergite IX modified into capsule with two elongate, asymmetrical and protruding lamellae (blades) that converge towards apex (Fig. 6E–F): left blade curved ventrally and posteriorly, long, flattened, weakly sclerotised, apex broadly rounded; right blade shorter, more strongly curved ventrally, apex rounded, undivided; tergite X strongly narrowed (Fig. 6F), longer than wide, split at base into two asymmetrical lobes projected posteriorly, one of lobes slightly shorter than other. Sternite VIII asymmetrical, distal margin deeply notched, sinuous, with sides projected posteriorly; sternite IX lamellar (Fig. 6F), weakly sclerotised, concealed underneath tergites VII and VIII.

**Fig. 7.** *Trypheridium nuristanicum* (Wittmer, 1956) nom. emend., paratype, ♀ (CANTH0013839, NHMB). **A.** Habitus, dorsal view. **B.** Terminal segments, ventral view. **C.** Terminal segments, dorsal view. **D.** Genitalia. **E.** Paratype label. Abbreviations: VII St=sternite VII; IX Tg=tergite IX; Agl=accessory gland; Bc=bursa copulatrix; Ov=oviduct; Sp=spermatheca; Vg=vagina. Scale bars: 0.5 mm. Line drawing (D) adapted from Brancucci (1985a).

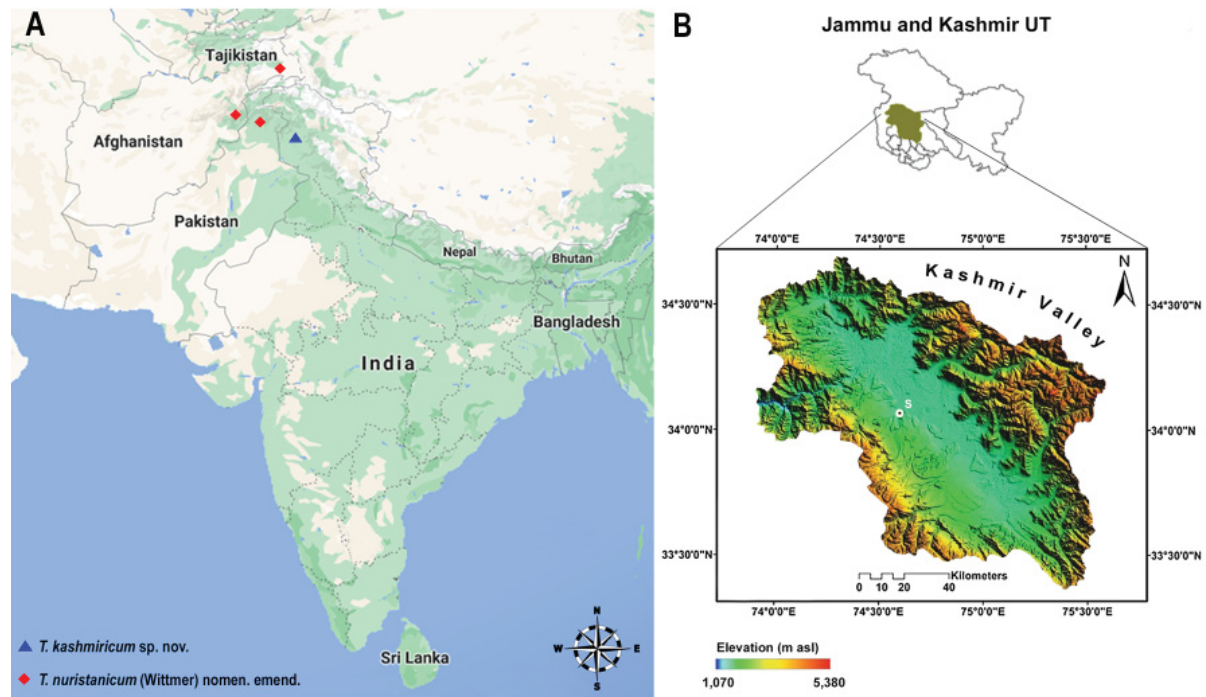

**AEDEAGUS.** Elongate, weakly sclerotised (Fig. 6G–I); left paramere absent, right paramere and prolongation of tegmen directed posteriorly. Right paramere elongated, ventral face with row of setae, apex flattened, forming rounded lobe; left prolongation of tegmen broad and lamellar, margins sinuous, apex truncate with tip pointing laterally, outer margin with fringe of setae. Median lobe membranous, short, not twisted, opening broad, located apically.

**Female** (Fig. 7)

Similar to males, except for eyes smaller, less protruding, interocular space 1.4 times larger than widest diameter of eye; antennae shorter, not reaching apex of elytra posteriorly. Sternite VII strongly and variably modified, elongate, projected distally into pair of forked lamellar projections, parallel to slightly divergent, apices rounded, sides of projections angulate at base or near mid length (Fig. 7B); sternite VIII subquadrate, broad and long, partly concealed by sternite VII, lateral margins arched, distal margin with rounded projecting lobe in middle tergite VIII convex, lateral margins slightly arched, distal margin broadly arched, concave, distal angles projected posteriorly, with glandular openings; tergite IX short and broad, distal margins slightly arched, concave (Fig. 7C). Genitalia membranous (Fig. 7D); vagina long and broad; bursa copulatrix elongate, wrinkled, spiralling; spermatheca formed by two tubular projections; accessory gland large, connected by long winding duct to the postero-dorsal part of bursa copulatrix.

**Remarks**

Brancucci (1985a) proposed *Trypheridium nuristanicus* (sic) as a new combination in his description of the neuter genus *Trypheridium*, of which it is the type species. He omitted to adjust the gender of the species name to agree with *Trypheridium*. The gender of *nuristanicus* (an adjective formed from the name of the type locality Nuristan in Afghanistan) is emended to *nuristanicum* to agree with the neuter Latin suffix *-idium* of *Trypheridium* (ICZN 1999, Art. 34.2). When proposing the genus, LeConte (1851)

**Fig. 8.** A. Global distribution of species of *Trypheridium* Brancucci, 1985. B. Sampling site of *Trypheridium kashmiricum* sp. nov.

did not give an etymology for *Trypherus*, but Gemminger & Harold (1869) defined the name as meaning “*debilis*” (weak, feeble, fragile, etc). “*Trypheridium*” is a diminutive, a ‘little *Trypherus*’.

### Distribution

Tajikistan; Afghanistan (Nuristan); Pakistan (Swat) (Fig. 8A).

### Discussion

The two species are very similar by the general morphology and coloration: both exhibit yellow and black regions on the head, a transversal band on the pronotum and a triangular patch on the elytra. However, the species can easily be distinguished by the external morphology of the last tergites and ventrites of the males and females and by the aedeagus. Males of *T. nuristanicum* have tergite IX with shorter blades, with the apex of the right blade entire, and tergite X divided into two short lobes, whereas those of *T. kashmiricum* sp. nov. have the tergite IX with longer and broader blades, with the right blade

**Fig. 9.** Variations in the VII<sup>th</sup> sternite of species of *Trypheridium* Brancucci, 1985, ♀♀. **A–B.** *Trypheridium kashmiricum* sp. nov. **C–D.** *Trypheridium nuristanicum* (Wittmer, 1956). Abbreviations: VII St=7<sup>th</sup> sternite; IX Tg=9<sup>th</sup> tergite. Scale bars: 0.5 mm.

divided at the apex, and tergite X divided into two very long and asymmetrical lobes. The aedeagi of the species are rather similar yet distinguished especially by the shape of the prolongation of the tegmen, which is much wider and abruptly narrowed before the apex in *T. nuristanicum*, and gradually narrowed in *T. kashmiricum* sp. nov. The females differ especially in the shape and number of the posterior projections of sternite VII: two projections in *T. nuristanicum* and three in *T. kashmiricum* sp. nov. The ventrite VII shows slight to strong differences among the specimens examined (Fig. 9). In *T. kashmiricum* sp. nov., the length and width of the lateral lobes vary and the distal margin of the median lobe may be truncate or notched (Fig. 9A–B). In *T. nuristanicum*, however, the differences in the shape, length, width and position of the lateral angles of the distal lobes are more remarkable (Fig. 9C–D). Four different shapes of sternite VII were observed in the four examined female paratypes from the same locality. A thorough examination of the ca 207 type specimens of *T. nuristanicum* might confirm if that structure is in fact broadly variable or if the type series of *T. nuristanicum* is composed of more than one species.

The strange morphology of *Trypherus nuristanicus* had already been pointed out by Magis & Wittmer (1974) and Brancucci (1980), and Brancucci (1985a) justified the elevation of the genus *Trypheridium* for that species based on morphological characters and on their widely disjunct distribution. Superficially, *Trypheridium* is very similar to *Trypherus*. Both genera are distinguished from the other Palaearctic and Oriental Ichthyurini genera *Ichthyurus* Westwood, 1848 and *Microichthyurus* Pic, 1919 especially in the smaller eyes, the antennal insertions separated (not juxtaposed), the pronotum more transverse, not remarkably convex, the males with sternite VIII not split into long prolongations, and tergite IX with well-developed blades directed ventrally and posteriorly (Brancucci 1983, 1985a). Despite the similarity between *Trypherus* and *Trypheridium*, according to Brancucci (1985a) the latter differs by their “aberrant” sexual characters, such as the blades of tergite IX in males, which are very elongate, the aedeagus without left paramere (right, according to Brancucci) and the median lobe membranous with a terminal opening (rather than preapical), and sternite VII of females elongate, mostly concealing the sternite VIII (which is uncommon in *Trypherus*). In addition, the males of species of *Trypherus* usually have conspicuous modifications on the mid legs, which can be short teeth in the trochanter (one species), the femora slightly to strongly swollen and/or curved (most species) and the tibiae sometimes broader in the apex. The mid legs of both species of *Trypheridium* are slender, without modifications.

## Acknowledgements

We are grateful to Matthias Borer and Isabelle Zürcher (NHMB) for facilitating us with the images of type material of *T. nuristanicum*. We are also grateful to two anonymous reviewers for their valuable suggestions to improve our manuscript.
