Abstract. The *Lasioglossum (Dialictus) gemmatum* species complex, also known as the *L. tegulare* species group and the *L. parvum* species complex, is a very common, widespread, diverse, and recognisable lineage of sweat bees, containing 22 previously described species and several known undescribed species. The species were recently revised for the eastern Nearctic region and the Greater Antilles, but remain poorly known in the western Nearctic along with most other *L. (Dialictus)*. These characteristics make it a prime candidate for revision in ongoing taxonomic work on the western Nearctic *L. (Dialictus)*. Here we present the results of this revision, including 10 new species descriptions, one new synonymy, a preliminary phylogeny, and keys to known Nearctic species. Species of the eastern Nearctic and a few primarily Neotropical species which can occur in the Nearctic are also included. We report that the *L. (D.) gemmatum* species complex is likely a monophyletic group arising from the *L. (D.) comulum* group, but that the enlarged tegula has arisen independently in at least two other *L. (Dialictus)* lineages, and it contains multiple cases of allopatric speciation. The following species are described as new: *Lasioglossum (Dialictus) angelicum* sp. nov., *L. (D.) deludens* sp. nov., *L. (D.) diabolicum* sp. nov., *L. (D.) eremum* sp. nov., *L. (D.) gloriosum* sp. nov., *L. (D.) indagator* sp. nov., *L. (D.) holzenthalii* sp. nov., *L. (D.) magnitegula* sp. nov., *L. (D.) profundum* sp. nov., and *L. (D.) rufodeludens* sp. nov. Previously undescribed males of *L. (D.) perparvum* (Ellis, 1914) and *L. (D.) pseudotegulare* (Cockerell, 1896) and the female of *L. (D.) gaudiale* (Sandhouse, 1924) are diagnosed and figured for the first time. *Lasioglossum (Dialictus) hunteri* (Crawford, 1932) is a new subjective junior synonym of *L. (D.) ellisiae* (Sandhouse, 1924). Pre-2022 specimen records of *L. (D.) hunteri* and *L. (D.) tegulariforme* (Crawford, 1907) are attributable to a heterogeneous mix of species, and records of *L. (D.) perparvum* are likely attributable to *L. (D.) deludens*.

Keywords. Apoidea, new species, phylogeny, taxonomy, tegula.

Introduction

The *Lasioglossum gemmatum* species complex is a lineage of *Lasioglossum* (*Dialictus*) Robertson, 1902 primarily characterized by the enlarged and often punctate tegula of both sexes. It was previously treated as the *L. tegulare* species group (Ellis 1914; Gibbs 2009a) and the *L. parvum* species complex (Gibbs 2018b; Gardner & Gibbs 2020) before it was recognised that *L. gemmatum* (Smith, 1853), as the oldest available name, should have precedence. The function of the enlarged tegula is unknown, but it has arisen frequently enough and persists in enough extant species to suppose that it has some adaptive value. In locusts, the tegula is an important proprioceptor for regulation of flight mechanics (Fischer & Ebert 1999). In bees, the tegula covers the basalar system, which is involved in wing movement (Snodgrass 1935; Pfau 2018). The shape of the tegula may be related to enhanced protection of the basalare and axillaries at the forewing base or a modified role in proprioception. Enlarged tegulae have evolved multiple times in distantly related Halictidae Thomson, 1869, including in the genera *Augochloropsis* Cockerell, 1897, *Dieunomia* Cockerell, 1899, and *Pseudapis* s. lat., at least one undescribed species of *Sphecodes*¹, in the *Lasioglossum* species *L. (Hemihalictus) glabriventre* (Crawford, 1907) and *L. (H.) kincaidii* (Cockerell, 1898), in *L. moffati* (Cockerell, 1920) and *L. trimeni* (Cockerell, 1920) of uncertain subgeneric placement and *L. (Chilalictus) albopilosum* Walker, 1995 within the series of ‘strong-veined’ *Lasioglossum*, and in some *L. (Dialictus)*. All of these *Lasioglossum* are restricted to the Western Hemisphere except for *L. moffati* and *L. trimeni* from Africa and *L. albopilosum* from Australia. Modified and enlarged tegulae are also seen in representatives of other bee families (Michener 2007). We hypothesize that the *L. gemmatum* species complex is a monophyletic group, but we notably exclude several other species of *L. (Dialictus)* with enlarged tegulae. These species are distinguishable by other characters and DNA barcodes, indicating that the enlarged tegula has multiple origins within *L. (Dialictus)* as it does in Halictidae.

This group is extremely widespread in the Western Hemisphere, ranging throughout most of North America (only absent from northern Canada) (Gardner & Gibbs 2022) and western South America from Colombia to Argentina and Chile (Engel 2000; unpublished data). It occurs even on remote islands including Hawaii (Tabor & Koch 2021), the Greater Antilles (Gibbs 2018b), Isla Socorro (unpublished data), and the Archipiélago de Juan Fernández (Engel 2000). This suggests a great dispersal ability, although the species occurring in Hawaii are known to be non-native there and may have been introduced by humans (Magnacca *et al.* 2013).

Species in the *L. gemmatum* complex generally follow the same patterns seen in *L. (Dialictus)* as a whole, including great abundance (especially with pan traps; see for example Campbell *et al.* 2007; Minckley 2008), recent and rapid evolution (Gibbs *et al.* 2012; Grab *et al.* 2019), and associated difficulties with cytochrome *c* oxidase subunit 1 (COI) barcode-based identification (Gibbs 2018a). Prior to 2021, there were 27 available names in the *L. gemmatum* complex (including 5 synonyms), suggesting a relatively high level of diversity. There are very few published descriptions of the biology, nest construction, or social behaviour of any species in the *L. gemmatum* complex, but those that exist indicate that species may have both eusocial and solitary nests. *Lasioglossum gemmatum* (Smith, 1853) and *L. parvum* (Cresson, 1865) were both found nesting in loose aggregations in sandy soil, with a single mated queen and 2–5 unmated workers per nest (Eickwort 1988). In contrast, Corbin *et al.* (2021) inferred *L. ellisiae* (Sandhouse, 1924) to have solitary nests based on wear and ovarian development in trapped specimens. *Lasioglossum* is ancestrally primitively eusocial (Gibbs *et al.* 2012), so the *L. gemmatum* complex as a rule likely makes eusocial nests, with the switch to solitary behaviour in *L. ellisiae* being derived or a

¹ This species was discovered by J. Gardner in collections from southern California at LACM. The tegula is shaped and densely punctured in both sexes in much the same way as in *L. tegulariforme* (Crawford, 1907). Mike Arduser (Missouri Department of Conservation), who has seen most of the *Sphecodes* type material, confirmed in personal communication that he has also seen specimens at UCRC and that no described species known to him has such a tegula, although some Palaearctic species have the tegula modified in other ways.

variable trait. However, the timing and frequency of reversions to solitary behaviour are impossible to determine without a known taxonomy, more studies of nesting behaviour, and a robust phylogeny.

The applied taxonomy of the *L. gemmatum* species complex in the Nearctic region has, historically, been treated as fairly simple. Despite the abundance of available names, only a few were frequently used and published in the literature. Prior to 2009, these included *L. hunteri* (Crawford, 1932) (for any specimen with a red metasoma), *L. tegulare* (Robertson, 1890) (for any specimen in the eastern United States), and *L. tegulariforme* (Crawford, 1907) (for most specimens in the western United States or Mexico). Some easily recognisable species from the southwestern United States and northern Mexico were also determined as *L. coactus* (Cresson, 1872) and *L. perparvum* (Ellis, 1914) in museum collections. The rest of the species were only known from the type material and, at most, a handful of other specimens.

It was suspected early on that the name *L. tegulariforme* was over-applied and included multiple species (Cockerell 1937). Michener (1937) made an effort to address this problem by describing *L. albuquerquense* Michener, 1937 and noting that the species included in Sandhouse (1924) as *L. tegulariforme* was probably actually this species. However, *L. albuquerquense* was not often identified after its description, and most western Nearctic specimens continued to be called *L. tegulariforme*. Over the next 70 years, species in the *L. gemmatum* complex continued to be consolidated into just the 3–5 most frequently used names. Michener (1951) (with input from P.H. Timberlake) synonymized *L. gaudiale* (Sandhouse, 1924) and *L. helianthi* (Cockerell, 1916) with *L. tegulariforme*, and Mitchell (1960) synonymized *L. ellisiae* (Sandhouse, 1924) and *L. lepidii* (Graenicher, 1927) with *L. tegulare*. Mitchell (1960) also described *L. surianae* (Mitchell, 1960), but apparently did not recognise it as a member of the *L. gemmatum* species complex and made no reference to the (admittedly only slightly) enlarged tegula.

It was not until a thorough revision of the *L. gemmatum* complex in the eastern United States and Canada by Gibbs (2009a) that its true diversity and complexity began to be revealed. Gibbs (2009a) resurrected *L. ellisiae* and *L. lepidii* from synonymy and described two new species which had previously been identified as *L. tegulare*. A revision of the *L. (Dialictus)* of Canada by Gibbs (2010) described one new species, *L. imbrex* Gibbs, 2010, which had previously been identified as *L. tegulariforme*. An update to that work (Gardner & Gibbs 2022) resurrected *L. gaudiale* and *L. helianthi* from synonymy, while recognising *L. imbrex* as a junior synonym of *L. helianthi* and *L. albuquerquense* as a junior synonym of *L. stictaspis* (Sandhouse, 1923), and defining *L. tegulariforme* in a much more restricted sense.

Based on this recent work, it is reasonable to expect *L. hunteri* and *L. tegulariforme*, as traditionally recognised, to contain multiple species. Examination of specimens from the western Nearctic region confirmed this expectation and revealed several undescribed species, some of which are surprisingly common and easily recognisable, yet have gone largely unnoticed. A revision of the *L. gemmatum* complex in the western Nearctic region was therefore considered a high priority in ongoing taxonomic work on *L. (Dialictus)*. Here we present results from that revision. Species in the eastern Nearctic region are also included because many of them also occur in the west, or there is some evidence that they may do so.

Material and methods

Taxon concept

The taxon concept for *L. (Dialictus)* follows the classification in Gibbs (2018b), and Gardner & Gibbs (2020, 2022). Species were delimited using an evolutionary species concept (Wiley & Mayden 2000) and integrative taxonomy (DeSalle *et al.* 2005); that is, species were considered as independent evolutionary lineages and were tested in a hypothesis-driven approach using at least two sources of data. The three most readily available data types, and the ones used in this work, are morphology, DNA, and geographic distributions.

Morphological examination and descriptions

Specimens were examined under a dissecting microscope at about $40\times$ magnification and illuminated with a standard desk lamp with a 13W fluorescent bulb (60W incandescent equivalent) set to one side. These bulbs provide very diffuse light, which is ideal for seeing punctures and surface sculpture, in contrast to more focused fibre optics or LEDs which often create too much glare on shiny integuments. Morphometric measurements were made with an ocular micrometer with both ends of the structure being measured kept in focus. Characters measured were a subset of those in Gardner & Gibbs (2020), with the addition of tegula maximum width and maximum length. Intertegular span (ITS), defined as the minimum distance between the tegulae (Cane 1987), was sometimes ambiguous due to the large posterior projection in some species which curves inward past the mesoscutum posterior margin, such that the minimum distance is far from the point at which ITS is usually measured. To facilitate comparisons with species with smaller tegulae, ITS was measured excluding any such projections.

Morphological terms and measurements follow standard usage in Michener (2007), with *Lasioglossum*-specific additions by Gibbs (2010) and Gardner & Gibbs (2020). Surface sculpture terms follow Harris (1979). Pubescence length and a few other characters are given in units of median ocellus diameters (OD) unless specified as lateral OD.

Puncture density is given in terms of the range of interspaces (IS) between punctures, in units of puncture diameters (PD). Punctures are said to be ‘crowded’ when there are few or no distinct interspaces; often this tight packing results in some punctures becoming polygonal rather than round, and this condition can blend into reticulate, rugulose, or areolate sculpture (Fig. 1A). This is contrasted with ‘dense ($IS < 1$ PD)’, in which all punctures are round and separated by at least narrow interspaces (Fig. 1B). The terms ‘dense’ and ‘sparse’ are an indication of whether most interspaces are toward the upper or lower end of the given range. ‘Moderately dense ($IS = 1–2$ PD)’ punctures are therefore separated mostly by about 1 PD, with a few interspaces up to 2 PD, and ‘moderately sparse ($IS = 1–2$ PD)’ punctures are mostly separated by about 2 PD (Fig. 1C). There are almost always a few punctures separated by only 1 or 2 PD, so a large range such as ‘sparse ($IS = 1–3$ PD)’ should be interpreted as closer to 3 PD on average (Fig. 1D).

Species accounts are organized into the following sections: 1) nomenclatural summary including synonymies; 2) **Diagnosis** for identification confirmation and comparison with similar species; 3) **Etymology** of the specific epithet; 4) **Material examined**; 5) **Description** (omitted for previously described species); 6) **Range** summarizing known occurrence records; 7) **Floral hosts**, sorted alphabetically by family, genus, species, and subspecies (note that records were obtained from specimen labels and do not distinguish pollen and nectar use); 8) **DNA barcodes** including barcode gap analysis and list of diagnostic

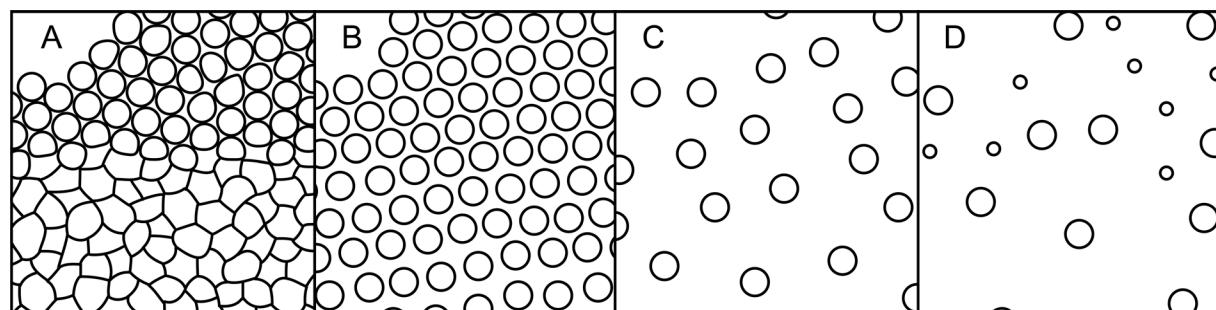

Fig. 1. Examples of punctuation in *Lasioglossum (Dialictus)* Robertson, 1902. **A.** Crowded ($IS = 0$ PD) with few or no distinct interspaces in upper half to ruguloso-punctate in lower half. **B.** Dense ($IS < 1$ PD) but distinct. **C.** Moderately dense in upper half to moderately sparse in lower half ($IS = 1–2$ PD). **D.** Sparse ($IS = 1–3$ PD) and diversopunctate in upper half.

nucleotides; 9) **Comments** for any additional discussion. For the material examined, label data is given in a standardized format. Estimates and author interpretations of missing or uncertain information are indicated by enclosure in square brackets ('[]'). Verbatim label data is only given for newly designated type material. New rows on a label are indicated with a single forward slash ('/') and additional labels are indicated with a double forward slash ('//'). Plant classification was updated for floral host lists using the World Flora Online database (WFO 2022).

Face, lateral and dorsal habitus, and metasoma images of all included species were generated with a Canon EOS 7D camera with MPE-65 lens (Canon, Ōta, Tokyo, Japan). Three wireless flash units were arranged at approximately 120° intervals around the specimen. Two tubes of diffusion paper were placed between the flash units and the specimen to scatter the light and reduce glare on the specimen. The camera was mounted on a StackShot system (Cognisys Inc., Traverse City, Michigan, United States) to obtain several images at varying focal depths, which were then processed for focus stacking in Helicon Focus software (Helicon Soft Ltd., Kharkiv, Ukraine). Male genitalia were illustrated in Illustrator CS5 software (Adobe Inc., San Jose, California, United States), while examining the genitalia using a microscope with ocular grid for scale reference.

DNA barcoding

DNA was extracted from hind legs of preserved specimens (or a hind leg and mid-leg for small specimens) by placing the tissue in individual tubes or wells, and then crushing it with a sterile pestle. Tubes or the pestle (for 96-well plates) were dipped in liquid nitrogen to cool the tissue and make it brittle. For small numbers of specimens (less than 30), DNA was extracted using DNeasy Blood & Tissue silica membrane spin column kits (Qiagen, Hilden, Germany) and a modified protocol developed for dried museum specimens by Crane (2013). For sets of 96 specimens, DNA was extracted using KingFisher Cell and Tissue DNA kits (Thermo Fisher Scientific Inc., Waltham, Massachusetts, United States), or MagMAX-96 DNA Multi-Sample kits (Thermo Fisher Scientific Inc., Waltham, Massachusetts, United States), on a KingFisher Flex magnetic particle processor (Thermo Fisher Scientific Inc., Waltham, Massachusetts, United States) and the manufacturer's default program. In all cases, the amount of elution buffer in the final step was reduced to increase the concentration of DNA.

PCR was run with 8.4–9.4 µL dH₂O, 5 µL 5X PCR buffer (Promega, Madison, Wisconsin, United States), 2.5 µl MgCl₂ (25 mM) (Promega, Madison, Wisconsin, United States), 5 µl dNTPs (1 mM each) (Promega, Madison, Wisconsin, United States), 0.125 µL GoTaq Flexi DNA polymerase (5 units/µL) (Promega, Madison, Wisconsin, United States), 1–2 µL DNA, and 1 µL of each primer (forward and reverse) (Integrated DNA Technologies, Coralville, Iowa, United States) for a 25 µL final reaction volume. Primers used were the BEEf-BEEr primer pair designed by Creedy *et al.* (2020) or the BarBeeF-MtD9 pair designed by Françoso & Arias (2013) for some older specimens, both of which amplify the standard 658 bp COI barcode region (Folmer *et al.* 1994). Reaction conditions followed those in Creedy *et al.* (2020) or Françoso & Arias (2013).

PCR products were checked for success by gel electrophoresis. Samples showing visible bands in the expected size range were purified with 0.4 µL of ExoSAP-IT (Thermo Fisher Scientific Inc., Waltham, Massachusetts, United States) per 1 µL DNA and sent for Sanger sequencing. Sequencing was performed by Eurofins MWG Operon (Toronto, Ontario, Canada) or University Core DNA Services at the University of Calgary (Alberta, Canada) prior to June 2019. Sequencing was performed in both forward and reverse directions. During early 2021, some samples were also sent to the Canadian Centre for DNA Barcoding (Guelph, Ontario, Canada) for complete processing from PCR to sequencing, due to a shortage of supplies.

Successful sequences were trimmed and aligned in Geneious ver. 8.1.7 (Kearse *et al.* 2012) and uploaded to the Barcode of Life Data System (BOLD; <http://www.boldsystems.org>) (Ratnasingham & Hebert 2007),

along with trace files and collection information. Distance metrics for DNA barcodes were calculated and diagnostic individual nucleotides were found using the maxInDist, nonConDist, and nucDiag functions in the spider package ver. 1.4-2 (Brown *et al.* 2012) in R ver. 4.0.0 (R Core Team 2020). All available *L. gemmatum* complex sequences ≥ 600 bp in length and with ≤ 5 ambiguous nucleotides were used for these analyses, after aligning the sequences first in BOLD and then making corrections by hand in Mesquite ver. 3.61 (Maddison & Maddison 2019). These sequences are available in the public BOLD dataset DS-GARDTEG ([10.5883/DS-GARDTEG](#)).

Some DNA barcodes were available from previous studies (Gibbs 2009a, 2010) and unpublished data from Jason Gibbs. These data were generated following the protocols in Gibbs (2009b).

Geographic distributions

Distribution maps were generated from all georeferenced specimen records included in Material examined, with some additional records extracted from Gibbs (2009a and 2010). For records without associated GPS coordinates, coordinates were estimated from the location written on the label by searching in Google Earth or Fuzzy Gazetteer (Kohlschütter [Internet]) and measuring distances from landmarks in Google Earth as necessary. Coordinates were usually estimated to two decimal degree digits, but up to three are given for localities that were possible to locate more precisely, or fewer for very vague localities such as entire counties.

To reduce bias from well-collected ‘hot spots’, each coordinate was rounded to the nearest 0.5 degree, duplicate records were removed, and then original unrounded coordinates associated with the remaining records were restored, except for species with ≤ 10 unique records, for which only exact duplicates were removed. These coordinates were imported into Maxent ver. 3.4.1 (Phillips *et al.* [Internet]), which plots known records in addition to a predicted distribution generated by maximizing entropy (more uniform spread) of a probability distribution of ecological niche occupancy, within constraints inferred from species presence records and environmental data (Phillips *et al.* 2006). Environmental data used included the 19 bioclimatic variables (based on temperature and precipitation), solar radiation, wind speed, and elevation available from WorldClim (Fick & Hijmans 2017) and soil classification available from the FAO/UNESCO Digital Soil Map of the World (FAO/UNESCO 2007). These variables were thought to be most relevant to *L. (Dialictus)* foraging and nesting. All environmental data were at the 2.5 minute spatial scale, as this is close to the maximum estimated precision of most of the georeferenced specimen records. Solar radiation and wind speed data were converted from 12 monthly averages to yearly mean, minimum, maximum, range, and standard deviation $\times 100$ in QGIS software (QGIS.org 2020) to be consistent with the WorldClim bioclimatic variables. The soil map was downloaded in vector format and rasterized to the 2.5 minute spatial scale in QGIS (QGIS.org 2020).

Maxent was run with soil type as categorical and all other variables as continuous, a regularization multiplier of 1, and complementary log-log (cloglog; the probability that at least one individual is present in a quadrat/pixel (Phillips *et al.* 2017)) as output. Soil classifications were unavailable for coastal regions near sea level and small islands. Records missing any environmental data were automatically excluded by Maxent but were manually added back on to the final maps (the model was not changed; only individual record markers were added). For three species with many records lacking soil data, such that excluding them drastically altered the predicted distribution, Maxent was instead run with all records but without soil classification as an environmental variable. Final maps were modified by recolouring and adding lakes, national borders, and state/province borders downloaded from Natural Earth (<https://www.naturalearthdata.com>; accessed 31 July 2020).

Phylogeny

To test the monophyly of the *L. gemmatum* species complex, a phylogenetic tree was generated using representatives of all species of the *L. gemmatum* complex, all species of the *L. comulum* group (see diagnosis of the *L. gemmatum* species complex below for a definition of this group), all other species of *Lasioglossum* having an enlarged tegula, and representatives of other major lineages of *L. (Dialictus)* from which high-quality COI sequences (≥ 600 bp and ≤ 5 ambiguous nucleotides) and morphological data were available. *Lasioglossum (Austrevylaeus) sordidum* (Smith, 1853) was also included as an outgroup and *L. (Hemihalictus) lustrans* (Cockerell, 1897) was included as a representative of *L. (Hemihalictus)* Cockerell, 1897. Sequences were downloaded and aligned from BOLD and the alignment was inspected and manually corrected in Mesquite ver. 3.61 (Maddison & Maddison 2019). Fifteen morphological characters were coded in a matrix ([Supp. file 1](#)) and added to the COI data.

A Markov Chain Monte Carlo (MCMC) tree search was performed in MrBayes ver. 3.2.7 (Ronquist *et al.* 2012) with the data partitioned by type (DNA or morphology). The DNA data used a GTR+I+ Γ with 4 rate parameters model of evolution (selected by ModelFinder (Kalyaanamoorthy *et al.* 2017)) and the morphological data used gamma-distributed rate variation. The MCMC search was performed with two simultaneous runs, 8 chains (1 cold chain and 7 heated chains), a temperature of 0.0375, and was run for 20 000 000 generations until convergence was achieved (standard deviation of split frequencies < 0.004). Other settings were the program defaults (sampling/diagnostics every 500/5000 generations with the first 25% of trees discarded as burn-in). The final 50% majority-rule consensus tree was rooted at the outgroup node.

Specimens examined

Type material and other specimens were examined from the following institutions and individuals. Abbreviations used throughout the rest of the text are given first, with the full name and curator/lender (if applicable) given in parentheses afterward.

Results

Phylogeny

The *L. gemmatum* species complex and *L. comulum* group together form a monophyletic group supported with 94% posterior probability (Fig. 2). Within this clade, the *L. gemmatum* species complex is also monophyletic, but with only 65% posterior probability. The *L. comulum* group is paraphyletic with respect to the *L. gemmatum* species complex.

Enlarged tegulae had at least four independent origins within *Lasioglossum*: once in *Hemihalictus*, once in *L. knereri* Gibbs, 2010, once in the *L. perdifficile* species complex, and once in the *L. gemmatum* species complex (Fig. 2). The *L. perdifficile* species complex may be para- or polyphyletic with respect to the clade including *L. hyalinum* (Crawford, 1907), which could imply a loss or a fifth origin of the enlarged tegula, but more data are needed to resolve the polytomy at the base of these clades.

Taxonomy

Ten new species in the *L. gemmatum* species complex from the western Nearctic region are here recognised and described. In total, 31 world species are recognised as valid in the *L. gemmatum* species complex, 18 of which occur in the continental western Nearctic region (19 including Hawaii). Fifteen of these have a dark metasoma and could have been determined as *L. tegulariforme* in the past (including the true *L. tegulariforme*), and seven have a red metasoma and were likely determined as *L. hunteri* in the past

(Table 1). Four species have variable metasoma colouration and could have been determined as either species in the past. The list below includes all 31 known species while the following revision treats only the 24 Nearctic species.

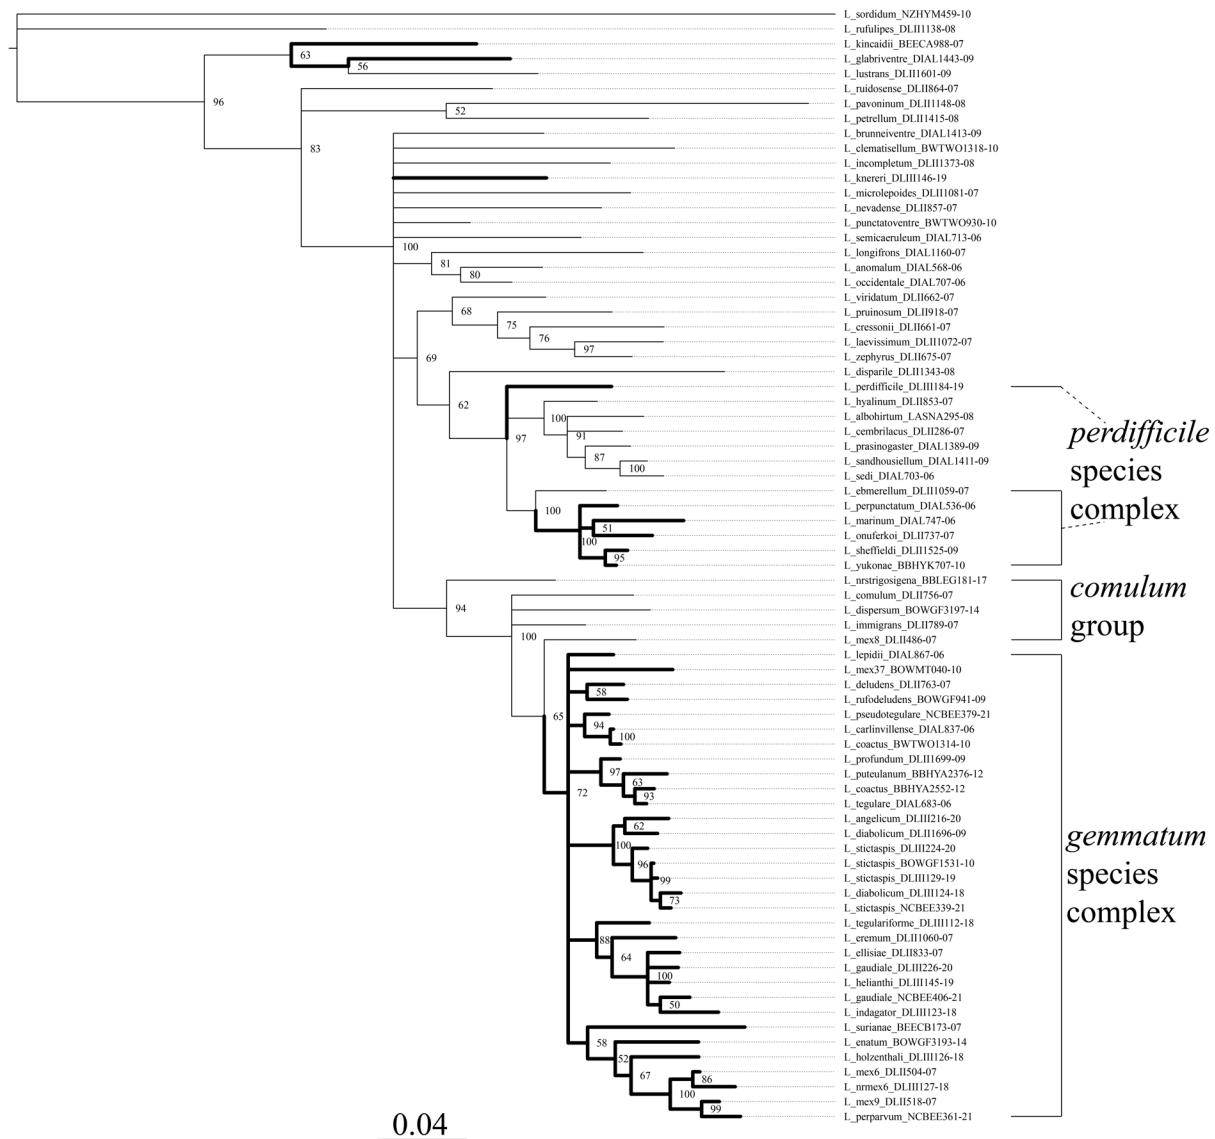

Fig. 2. 50% majority-rule consensus tree of species of *Lasioglossum* Curtis, 1833 with enlarged tegulae and representatives of other major lineages, based on 654-bp COI sequences and 15 morphological characters. MCMC tree search was performed in MrBayes ver. 3.2.7 using a GTR+I+Γ4 model for the molecular data, gamma-distributed rate variation for the morphological data, partitioning by data type, two simultaneous runs with 8 chains each, temperature of 0.0375, 20 000 000 generations, and *L. sordidum* (Smith, 1853) set as the outgroup (other settings program defaults). Node labels are posterior probabilities. Taxa names are followed by their BOLD accession numbers. **Bold** branches on the tree are species with enlarged tegulae.

Table 1. Currently recognised species in the *L. gemmatum* species complex of the western Nearctic region, according to metasoma colour and which species each would have most likely been determined as prior to 2010.

Dark metasoma (traditional ‘ <i>L. tegulariforme</i> ’)	<i>L. angelicum</i> sp. nov., <i>L. coactus</i> , <i>L. deludens</i> sp. nov., <i>L. diabolicum</i> sp. nov., <i>L. ellisiae</i> , <i>L. eremum</i> sp. nov., <i>L. gaudiale</i> , <i>L. helianthi</i> , <i>L. holzenthalii</i> sp. nov., <i>L. magnitegula</i> sp. nov., <i>L. perparvum</i> , <i>L. profundum</i> sp. nov., <i>L. pseudotegulare</i> , <i>L. stictaspis</i> , <i>L. tegulariforme</i>

Lasioglossum gemmatum species complex

Species included

Lasioglossum angelicum sp. nov., *L. busckielum* (Cockerell, 1915), *L. carlinvillense* Gibbs, 2009, *L. coactus* (Cresson, 1872), *L. cupreicollis* (Friese, 1917), *L. deludens* sp. nov., *L. diabolicum* sp. nov., *L. ellisiae* (Sandhouse, 1924), *L. enatum* Gibbs, 2018, *L. eremum* sp. nov., *L. fernandezis* Engel, 2000, *L. gaudiale* (Sandhouse, 1924), *L. gemmatum* (Smith, 1853), *L. gloriosum* sp. nov., *L. helianthi* (Cockerell, 1916), *L. holzenthalii* sp. nov., *L. indagator* sp. nov., *L. lepidii* (Graenicher, 1927), *L. magnitegula* sp. nov., *L. monense* Gibbs, 2018, *L. parvum* (Cresson, 1865), *L. paululum* (Sandhouse, 1924), *L. perparvum* (Ellis, 1914), *L. profundum* sp. nov., *L. pseudotegulare* (Cockerell, 1896), *L. puteulanum* Gibbs, 2009, *L. rufodeludens* sp. nov., *L. stictaspis* (Sandhouse, 1923), *L. surianae* (Mitchell, 1960), *L. tegulare* (Robertson, 1890), and *L. tegulariforme* (Crawford, 1907).

Diagnosis

Both sexes in the *L. gemmatum* complex have the tegula enlarged (reaching the posterior margin of the mesoscutum in dorsal view or nearly so), usually strongly punctate, and with the inner posterior margin straight or concave; about 50% of clypeus projecting below suborbital tangent; and T1 without tomentum. Additionally, females have the propodeum with a distinct oblique carina, and males have the mesepisternum and often propodeum lateral face shiny with large, distinct punctures, and metasomal sterna with moderately sparse pubescence 1–2 OD long.

Some members of the *L. perdifficile* complex (defined in Gardner & Gibbs 2022) have a similar tegula, but these have more than 50% of the clypeus projecting below the suborbital tangent, females with propodeum oblique carina absent, and T1 with lateral tomentum. Some atypical specimens of *L. knereri* Gibbs, 2010 from California (possibly representing a cryptic species) also have a similar tegula, but have the propodeum without a distinct oblique carina, the metasomal terga all without appressed tomentum, and males have the metasomal sterna with very long and dense scopula-like pubescence (>2 OD).

Lasioglossum comulum Michener, 1951, *L. dispersum* Gibbs, 2018, *L. immigrans* Gardner & Gibbs, 2022, *L. strigosigena* Michener, 1954, and several undescribed species have the tegula small, ovoid, and impunctate, which is standard for most *L. (Dialictus)*, but resemble the *L. gemmatum* complex in most other characters. Additionally, DNA barcodes of these two species groups are very similar and suggest a close relationship. These species are informally defined as the *L. comulum* group. The *L. comulum*

group appears to be an evolutionary grade from which the *L. gemmatum* complex is derived (Fig. 2), but additional taxon sampling and more molecular data are needed to resolve their relationship with more certainty.

Lasioglossum stictaspis species complex

Species included

Lasioglossum angelicum sp. nov., *L. cupreicollis* (Friese, 1917), *L. diabolicum* sp. nov., *L. paululum* (Sandhouse, 1924), and *L. stictaspis* (Sandhouse, 1923).

Diagnosis

The *L. stictaspis* species complex is a subset of the *L. gemmatum* complex defined by a cluster of highly similar DNA barcodes (BOLD BINs: ABX4912, AEC8768) containing numerous ‘mixture’ associations (as in Ratnasingham & Hebert 2013). No single combination of morphological characters reliably distinguishes the group, but most members have the tegula relatively large compared to most other species of *L. gemmatum* complex (maximum length half or more ITS and reaching or exceeding posterior margin of mesoscutum in dorsal view) and densely punctate (IS < 1 PD) (except *L. diabolicum* sp. nov.), face short (length/width ratio usually < 0.83 in females and < 0.86 in males), gena narrower than eye in lateral view, mesoscutum with abundant plumose pubescence about 1 OD long, T2–T4 with abundant tomentum and dense simple setae, and males with dense tomentum covering the face up to level of eye emargination.

Lasioglossum cupreicollis is included in this group with some trepidation, as the holotype was not available for examination and no known DNA barcodes are available. However, images of the holotype of *Halictus goethalsi* Cockerell, 1928 (considered a junior synonym of *L. cupreicollis* by Michener 1954) were seen, and it closely resembles some members of the *L. stictaspis* complex. One male specimen from Colombia also has a DNA barcode available and clearly belongs to this group, indicating that its distribution extends into South America.

Lasioglossum pseudotegulare is morphologically similar to the *L. stictaspis* complex except for its longer face (length/width ratio usually ≥ 0.83 in females and ≥ 0.86 in males), but its DNA barcodes are unique and highly divergent, and it is therefore excluded.

Lasioglossum (Dialictus) angelicum sp. nov.

[urn:lsid:zoobank.org:act:7D4DB588-1714-46C7-AAC0-8E44E2AF44A5](https://doi.org/10.1544/7D4DB588-1714-46C7-AAC0-8E44E2AF44A5)

Figs 3–5, 76A, 78C, 86B, 87A, 90B, 92B, 93B, 110B

Diagnosis

Females of *L. angelicum* sp. nov. have the tegula very large (exceeding posterior margin of mesoscutum in dorsal view) and densely punctate (IS < 1 PD), with inner posterior margin strongly concave and forming a posterior projection about the size of 1 lateral OD; scutellum densely punctate (IS < 1 PD); metapostnotum shiny with strong anastomosing rugae reaching posterior margin; T1 shiny and distinctly, moderately densely punctate (IS = 1–2 PD), usually with some fine punctures extending onto apical rim; face short (length/width ratio ≤ 0.83); gena slightly shorter than eye in lateral view; and tegula and metasoma black. Often, the mesoscutum is relatively sparsely and coarsely punctate (posterior half with IS = 1–3 PD in centre and only 2–3 punctures present between posterior end of parapsidal line and lateral edge of mesoscutum) and shiny at least on lateral and posterior margins, but a few specimens have the mesoscutum dull and more densely punctate; these specimens are difficult to distinguish from *L. helianthi*.

Females of *L. angelicum* sp. nov. are most similar to those of *L. gaudiale*, *L. helianthi*, *L. pseudotegulare*, and *L. tegulariforme*. Females of *L. gaudiale* and *L. helianthi* have the tegula slightly smaller (reaching but not exceeding posterior margin of mesoscutum in dorsal view) and sometimes more sparsely punctate (IS ≥ 1 PD laterally at midlength). In addition, females of *L. gaudiale* have the gena about as wide as eye in lateral view, scutellum often moderately sparsely punctate (IS = 1–2 PD), and metapostnotum usually with subparallel rugae not reaching posterior margin. Females of *L. helianthi* have the T1 anterior slope usually coriarious and mesoscutum posterior half entirely densely punctate (IS < 1 PD). Females of *L. pseudotegulare* have the face slightly longer (length/width ratio ≥ 0.83) and metapostnotum dull with fine, subparallel rugae. Females of *L. tegulariforme* have T1 with an impunctate median line about 1 OD wide and mesoscutum posterior half entirely densely punctate (IS < 1 PD). Some females of other, unknown species in the *L. stictaspis* species complex can be very similar, but all have the T1 disc more finely and sparsely punctate (IS = 1–4 PD) and/or coriarious, and often have the tegula and metasoma red-orange.

Males of *L. angelicum* sp. nov. have the tegula very large (as in the female); metapostnotum shiny with strong rugae; mesepisternum densely punctate (IS < 1 PD) at least in ventral half; mesoscutum usually moderately densely punctate (IS = 1–2 PD); T1 shiny; discs of T1–T2 uniformly finely and moderately densely punctate (IS = 1–2 PD) with some punctures extending onto apical rims; face short (length/width ratio ≤ 0.86); and tegula black.

Males of *L. angelicum* sp. nov. are most similar to those of *L. helianthi*, *L. pseudotegulare*, and *L. tegulariforme*. Males of *L. helianthi* have the tegula smaller (not exceeding posterior margin of mesoscutum in dorsal view) with a narrow posterior point much smaller than 1 lateral OD and mesoscutum densely punctate (IS ≤ 1 PD). Males of *L. pseudotegulare* have the face slightly longer (length/width ratio usually > 0.86) and discs of T1–T2 more densely punctate (IS ≤ 1 PD). Males of *L. tegulariforme* have the disc of T1 more sparsely punctate than T2, T1–T2 apical rims impunctate, and mesoscutum densely punctate (IS ≤ 1 PD). Some males of other, unknown species in the *L. stictaspis* species complex can be very similar, but usually have the mesepisternum ventral half more sparsely punctate (IS = 1–2 PD), T1 coriarious at base, or tegula red-orange. A few specimens may be morphologically indistinguishable and can only be separated by geography, DNA barcodes, or associated females.

Etymology

The specific epithet ‘*angelicum*’ is a Latin adjective derived from the noun ‘*angelus*’ (angel) plus the adjectival suffix ‘-icūm’ (having the quality of). It is a reference to the type locality of the Los Angeles basin, where this species is common. An appropriate translation would be the angelic sweat bee.

Description

Female

COLOURATION. Head and mesosoma blue to blue-green; clypeus apex black; labrum black; mandible orange with black base and red apex; flagellum black dorsally, orange ventrally. Pronotal lobe black; legs black with femur-tibia joints and tarsi dark reddish brown; tegula dark reddish brown; wing membrane hyaline, veins with subcosta dark brown, otherwise lighter brown. Metasoma black with rims of terga and sterna broadly translucent yellow.

PUBESCENCE. Body pile colour white to pale yellow. Tomentum dense on lower paraocular area, gena adjacent to compound eye, pronotal collar and lobe, space between pronotal lobe and tegula, T2–T3 basolaterally, and T4 throughout. Mesoscutum pubescence thin to moderately plumose. Wing setae dark, short and dense. Acinarial fan complete, dense. T2 fringes dense, T3 fringes dense.

SURFACE SCULPTURE. Clypeus shiny, with punctures moderately sparse (IS = 1–2 PD), becoming larger in apical half; supraclypeal area shiny, with punctures moderately dense (IS = 1–2 PD); paraocular area shiny, with punctures dense (IS < 1 PD), sparser around antenna socket (IS ≤ 1 PD); frons reticulate, with

punctures fine, crowded (IS = 0 PD); vertex shiny, with punctures dense laterally (IS < 1 PD), sparse medially (IS = 1–3 PD); gena shiny, with punctures fine, sparse (IS = 1–3 PD); postgena lineolate, becoming shiny anteriorly. Tegula punctures dense (IS < 1 PD); mesoscutum weakly tessellate, with punctures moderately dense (IS = 1–2 PD), becoming dense on lateral and posterior margins (IS < 1 PD); scutellum weakly tessellate, with punctures dense marginally (IS < 1 PD), moderately sparse submedially (IS = 1–2 PD); metapostnotum shiny, becoming tessellate posteriorly, with rugae strong, anastomosing, reaching posterior margin; preepisternum rugulose; hypoepimeron shiny, with punctures crowded (IS = 0 PD); mesepisternum imbricate, with punctures dense (IS ≤ 1 PD); metepisternum weakly rugulose; propodeum lateral surface weakly tessellate, becoming weakly rugulose dorsally and anteriorly, posterior surface weakly tessellate. T1 anterior slope shiny, disc shiny, with punctures fine, moderately dense (IS = 1–2 PD), absent in large subapicolateral boss and on rim; T2 disc shiny, with punctures fine, moderately dense (IS = 1–2 PD), apical rim shiny, with punctures minute, sparse (IS = 1–4 PD).

STRUCTURE. Face length/width ratio 0.81 (± 0.02 SD); clypeus apicolateral denticles low rounded knobs; gena/eye width ratio 0.88 (± 0.07 SD). Pronotal angle slightly obtuse, nearly right-angled; intertegular span 0.85 (± 0.05 SD) mm; mesoscutum length/width ratio 0.9 (± 0.03 SD); mesoscutum/scutellum length ratio 2.87 (± 0.08 SD); scutellum/metanotum length ratio 1.62 (± 0.1 SD); metanotum/metapostnotum length ratio 0.77 (± 0.06 SD); forewing with 3 submarginal cells; tegula enlarged, exceeding posterior margin of mesoscutum; inner margin concave; tegula length 0.46 (± 0.03 SD) mm, width 0.23 (± 0.02 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina strong, straight. T2 depressed apical rim less than 50% of tergum. (n = 10)

VARIATION. The mesoscutum is occasionally completely tessellate and/or densely punctate in posterior half (IS ≤ 1 PD); the mesepisternum can vary from shiny to dull and imbricate; the T1 anterior slope is sometimes weakly coriarious; and the T1 apical rim is often punctate below the subapicolateral boss.

Male

COLOURATION. Head and mesosoma blue to blue-green; clypeus apex black; labrum black; mandible orange, becoming red at apex and black at base; flagellum black dorsally, light brown or orange ventrally. Pronotal lobe black; legs black with tarsi dark brown; tegula black; wing membrane hyaline, veins dark brown. Metasoma black with depressed apical rims of terga and sterna translucent brown.

PUBESCENCE. Body pile colour white. Tomentum dense on face below eye emargination, pronotal angle and lobe, and space between pronotal lobe and tegula; sparse on metepisternum. Mesoscutum pubescence simple to sparsely plumose. Wing setae dark, short and dense. Sterna pubescence short (0.5–1.5 OD), moderately plumose, sparse.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense (IS < 1 PD); supraclypeal area shiny, with punctures dense (IS ≤ 1 PD); paraocular area shiny, with punctures dense (IS < 1 PD); frons reticulate, with punctures crowded (IS = 0 PD); vertex shiny to imbricate, with punctures crowded laterally (IS = 0 PD), moderately dense medially (IS = 1–2 PD); gena shiny anteriorly, imbricate-lineate posteriorly, with punctures dense anteriorly (IS ≤ 1 PD), obscure posteriorly; postgena imbricate-lineate, becoming shiny anteriorly. Tegula punctures crowded (IS = 0 PD), sometimes slightly sparser medially; mesoscutum shiny, becoming weakly tessellate anteromedially, with punctures moderately dense (IS = 1–2 PD), becoming crowded marginally (IS = 0 PD); scutellum shiny, with punctures dense (IS < 1 PD), becoming sparser medially (IS = 1–2 PD); metanotum areolate; metapostnotum shiny to finely reticulate, with rugae strong, subparallel, reaching posterior margin; preepisternum areolate; hypoepimeron shiny, with punctures crowded (IS = 0 PD); mesepisternum shiny, with punctures dense (IS < 1 PD); metepisternum areolate; propodeum lateral surface weakly rugulose, with punctures dense (IS < 1 PD), posterior surface rugulose, becoming shiny and densely punctate medially (IS < 1 PD). T1 anterior slope shiny, disc shiny,

with punctures fine, moderately sparse ($IS = 1\text{--}2 PD$), absent in large subapicolateral boss and on rim medially; T2 disc shiny, with punctures fine, moderately sparse ($IS = 1\text{--}2 PD$), apical rim shiny, with punctures absent.

STRUCTURE. Face length/width ratio 0.83 ($\pm 0.02 SD$); gena/eye width ratio 0.77 ($\pm 0.06 SD$). Pronotal angle obtuse; intertegular span 0.71 ($\pm 0.04 SD$) mm; mesoscutum length/width ratio 0.95 ($\pm 0.03 SD$); mesoscutum/scutellum length ratio 2.8 ($\pm 0.14 SD$); scutellum/metanotum length ratio 1.76 ($\pm 0.14 SD$); metanotum/metapostnotum length ratio 0.7 ($\pm 0.09 SD$); forewing with 3 submarginal cells; tegula enlarged, exceeding posterior margin of mesoscutum in dorsal view; inner posterior margin strongly concave, with broadly rounded projection angled toward axilla posteriorly; tegula length 0.44 ($\pm 0.02 SD$) mm, width 0.22 ($\pm 0.01 SD$) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina absent. ($n = 10$)

GENITALIA. As in Fig. 76A. Gonocoxite about 1.8 times as broad as gonostylus. Gonostylus weakly boot-shaped, with a small sharply angled concavity on outer margin and straight on inner margin, with sparse short setae apically. Penis valves parallel, with moderately long appressed setae dorsolaterally in basal half. Retrorse lobe rounded, about 2.75 times as long as broad, with sparse short setae on apical and dorsal margins.

VARIATION. The mesoscutum punctuation can vary from mostly dense ($IS \leq 1 PD$) to sparse ($IS = 1\text{--}3 PD$), the mesepisternum dorsal half is sometimes more sparsely punctate ($IS = 1\text{--}2 PD$), and the T2 apical rim is often punctate on the centre of the basal margin.

Fig. 5. Georeferenced collection records of *Lasioglossum (D.) angelicum* sp. nov. (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

Range

Los Angeles basin and south along the Pacific coast to San Diego, west to Malibu (Fig. 5).

Floral hosts

APIACEAE Lindl.: *Pimpinella* L.: *P. anisum* L. • ASTERACEAE Bercht. & J.Presl: *Encelia* Adans.: *E. farinosa* A.Gray ex Torr.

DNA barcodes

Five confirmed sequences available (BOLD process IDs: DLIII214-20, DLIII215-20, DLIII216-20, DLIII223-20, NCBEE465-21). These sequences are identical (0% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. diabolicum* sp. nov. (1.84% minimum interspecific p-distance). Four fixed nucleotide substitutions distinguish *L. angelicum* sp. nov. from all other Nearctic species of the *L. gemmatum* complex: 222(C), 237(A), 420(G), and 525(C) ([Supp. file 2](#)).

Lasioglossum (Dialictus) carlinvillense Gibbs, 2009

Figs 6–8

Lasioglossum (Dialictus) carlinvillense Gibbs, 2009a: 28 (holotype, ♀, deposited in PCYU, examined).

Lasioglossum (Dialictus) carlinvillense – Gibbs 2011: 25, 32 (key to species), 65 (review).

Diagnosis

Females of *L. carlinvillense* have the tegula relatively small (reaching but not exceeding posterior margin of mesoscutum), moderately densely punctate (IS \leq 1 PD), and with inner posterior margin straight or weakly concave; mesoscutum entirely dull and tessellate; metapostnotum with strong subparallel rugae reaching posterior margin; mesepisternum strongly imbricate with crowded punctures (IS = 0 PD), inner metatibial spur with only two branches, and T1–T3 flat in lateral view. They are most similar to those of *L. coactus* and *L. tegulare*, both of which have the inner metatibial spur with 3–4 branches. Females of *L. coactus* also have T1–T3 distinctly convex in lateral view.

The male of *L. carlinvillense*, if correctly associated, may be morphologically indistinguishable from *L. tegulare* (see Comments).

Etymology

Gibbs (2009a) named this species after the type locality of Carlinville, Illinois, combined with the Latin adjectival suffix ‘-ense’ (indicating association with a place).

Material examined

Holotype

UNITED STATES – Illinois • ♀; Macoupin Co., east of Carlinville; 39.2787° N, 89.7961° W; 25 Jun. 2006; J. Gibbs and C. Sheffield leg.; PCYU.

Other material

UNITED STATES – Alabama • 1 ♀; Sheffield; [34.77° N, 87.7° W]; 4 Aug. 1944; G.E. Bohart leg.; BBSL700639 • 1 ♂; ibid.; 4 Aug. 1944; G.E. Bohart leg.; BBSL700633. – Illinois • 1 ♀; Carlinville; 39.2787° N, 89.8898° W; 24 Jun. 2006; J. Gibbs leg.; PCYU • 1 ♀; Dubois; [38.22° N, 89.21° W]; 8 Aug. 1917; INHS • 1 ♀; Litchfield; 39.1484° N, 89.66696° W; 25 Jun. 2006; C. Sheffield leg.; PCYU.

Range

Illinois to Alabama (Fig. 8).

Floral hosts

None recorded.

DNA barcodes

Three confirmed sequences available (BOLD process IDs: DIAL728-06, DIAL832-06, DIAL837-06). These sequences are identical (0% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. coactus* (0.15% minimum interspecific p-distance). No fixed nucleotide substitutions distinguish *L. carlinvillense* from all other species of the *L. gemmatum* complex or closely related species.

Comments

Rare. *Lasioglossum carlinvillense* was described from only four female specimens, all from Illinois. These specimens have similar DNA barcodes to several sequences from Colorado and Texas for which the associated specimens could not be located and examined. These sequences probably belong to *L. coactus*, which shares the same BIN as *L. carlinvillense*, but the possibility that *L. carlinvillense* ranges further west into Colorado cannot be ruled out.

Two additional female specimens with only two metatibial spur branches were discovered in the current work, both from Alabama. One of these is much larger than the other known specimens of *L. carlinvillense* and is believed to be an atypical *L. puteulanum*. The other is morphologically indistinguishable from

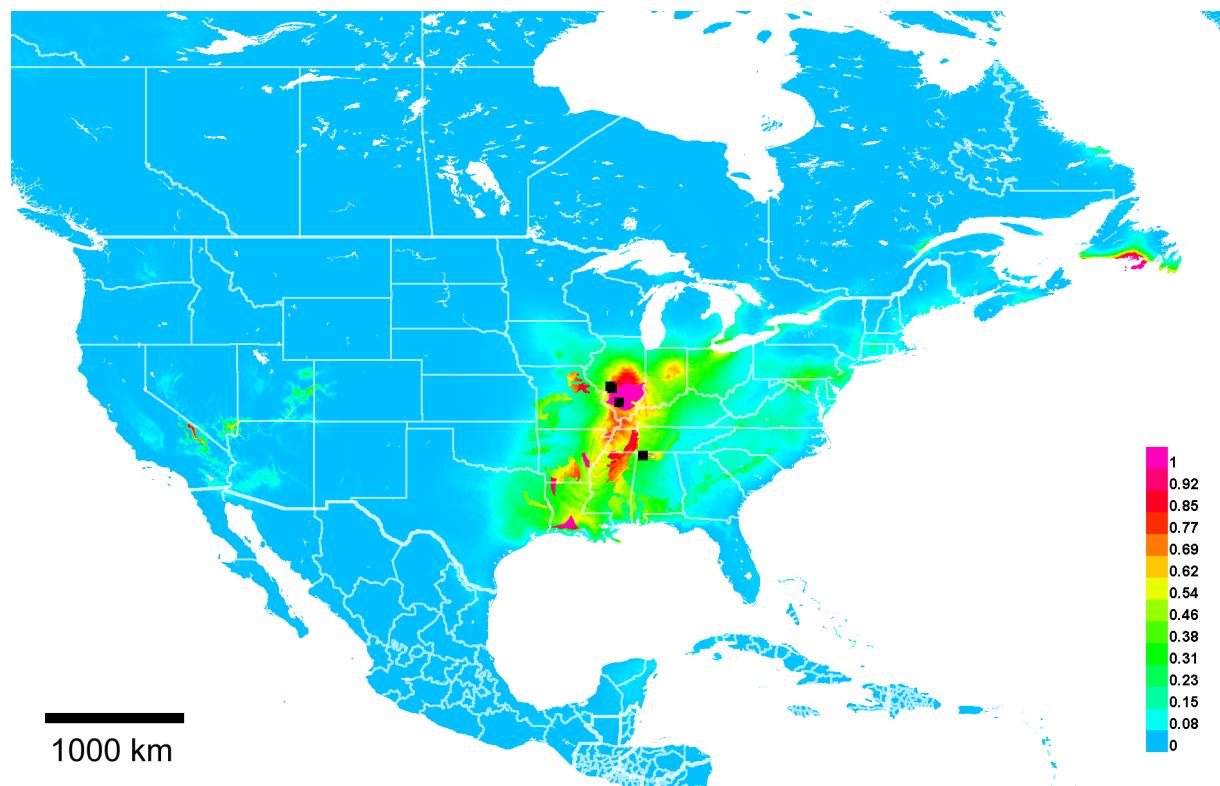

Fig. 8. Georeferenced collection records of *Lasioglossum (D.) carlinvillense* (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

other *L. carlinvillense* and may truly be a new record. There is one male from the same collection event as this specimen, but it is morphologically indistinguishable from *L. tegulare*, and whether it is the hitherto unknown male of *L. carlinvillense* is uncertain. These specimens are far too old to attempt DNA barcoding, but fresh material from Alabama could help resolve their status.

It is possible that *L. carlinvillense* is merely an aberrant form of *L. tegulare* or a hybrid of *L. tegulare* and *L. coactus*. *Lasioglossum carlinvillense* and *L. tegulare* are apparently morphologically indistinguishable except by the metatibial spur and the slightly smaller size of the former. The fact that *L. coactus* also shares a BIN with *L. tegulare* suggests that introgression could have occurred between these two species. A possible explanation, then, is that the BIN corresponding to *L. carlinvillense* is the “natural” COI sequence for *L. coactus*, and the *L. coactus* sequences in the *L. tegulare* BIN are a result of introgression. Similarly, the *L. carlinvillense* sequences could then be *L. tegulare* which acquired *L. coactus* COI sequences through introgression. More evidence is needed to test this hypothesis.

***Lasioglossum (Dialictus) coactus* (Cresson, 1872)**

Figs 9–11, 76B, 82B, 85A, 86A, 106A, 107A

Halictus coactus Cresson, 1872: 254 (lectotype designated in Cresson (1916), ♀, deposited in ANSP, type no. 2123, examined).

Halictus coactus – Cresson 1887: 292 (catalogue); 1916: 107 (lectotype designation). — Dalla Torre 1896: 58 (catalogue).

Halictus (Chloralictus) coactus – Ellis 1914: 100, 101 (comparison to *jamaicae* = *gemmatum* and *tegulare*), 103 (comparison to *perparvum*).

Lasioglossum (Chloralictus) coactum (!) – Michener 1951: 1112 (catalogue). — Scott *et al.* 2011: 29 (checklist).

Dialictus coactus – Hurd 1979: 1965 (catalogue). — Moure & Hurd 1987: 95 (catalogue).

Diagnosis

Females of *L. coactus* have T1–T3 distinctly convex in lateral view (although not as strongly so as in the male), with apical rims strongly depressed, shiny, and impunctate or very sparsely punctate, contrasting with densely punctate discs (IS \leq 1 PD); T3 with dense and complete subapical band of tomentum; tegula relatively small (reaching but not exceeding posterior margin of mesoscutum) and densely punctate (IS \leq 1 PD); metapostnotum usually shiny with strong anastomosing rugae reaching posterior margin (rarely dull with fine rugae); mesepisternum imbricate with punctures often dense (IS $<$ 1 PD) but distinctly separated and round (sometimes crowded (IS = 0 PD)); and inner metatibial spur with 3–4 branches.

Females of *L. coactus* are most similar to those of *L. carlinvillense* and *L. tegulare*, both of which have T1–T3 flat in lateral view. In addition, females of *L. carlinvillense* have the inner metatibial spur with only 2 branches and *L. tegulare* have the mesepisternum with crowded indistinct punctures (IS = 0 PD) or rugulose. Some species in the *L. stictaspis* species complex (particularly *L. stictaspis* s. str.) are also similar, but have T1–T3 flat in lateral view and more finely and sparsely punctate (IS = 1–3 PD), the mesepisternum shiny, and/or metapostnotum dull with fine, subparallel rugae.

Males of *L. coactus* have T1–T4 very strongly convex, with abruptly depressed, shiny, impunctate apical rims contrasting with densely punctate discs (IS $<$ 1 PD); tegula relatively small (reaching but not exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin weakly concave, and somewhat densely punctate (IS \leq 1 PD); and mesepisternum densely punctate (IS $<$ 1 PD). They are not likely to be confused with any other species so long as T1–T4 are visible, but specimens with broken metasomas may be indistinguishable from *L. tegulare*.

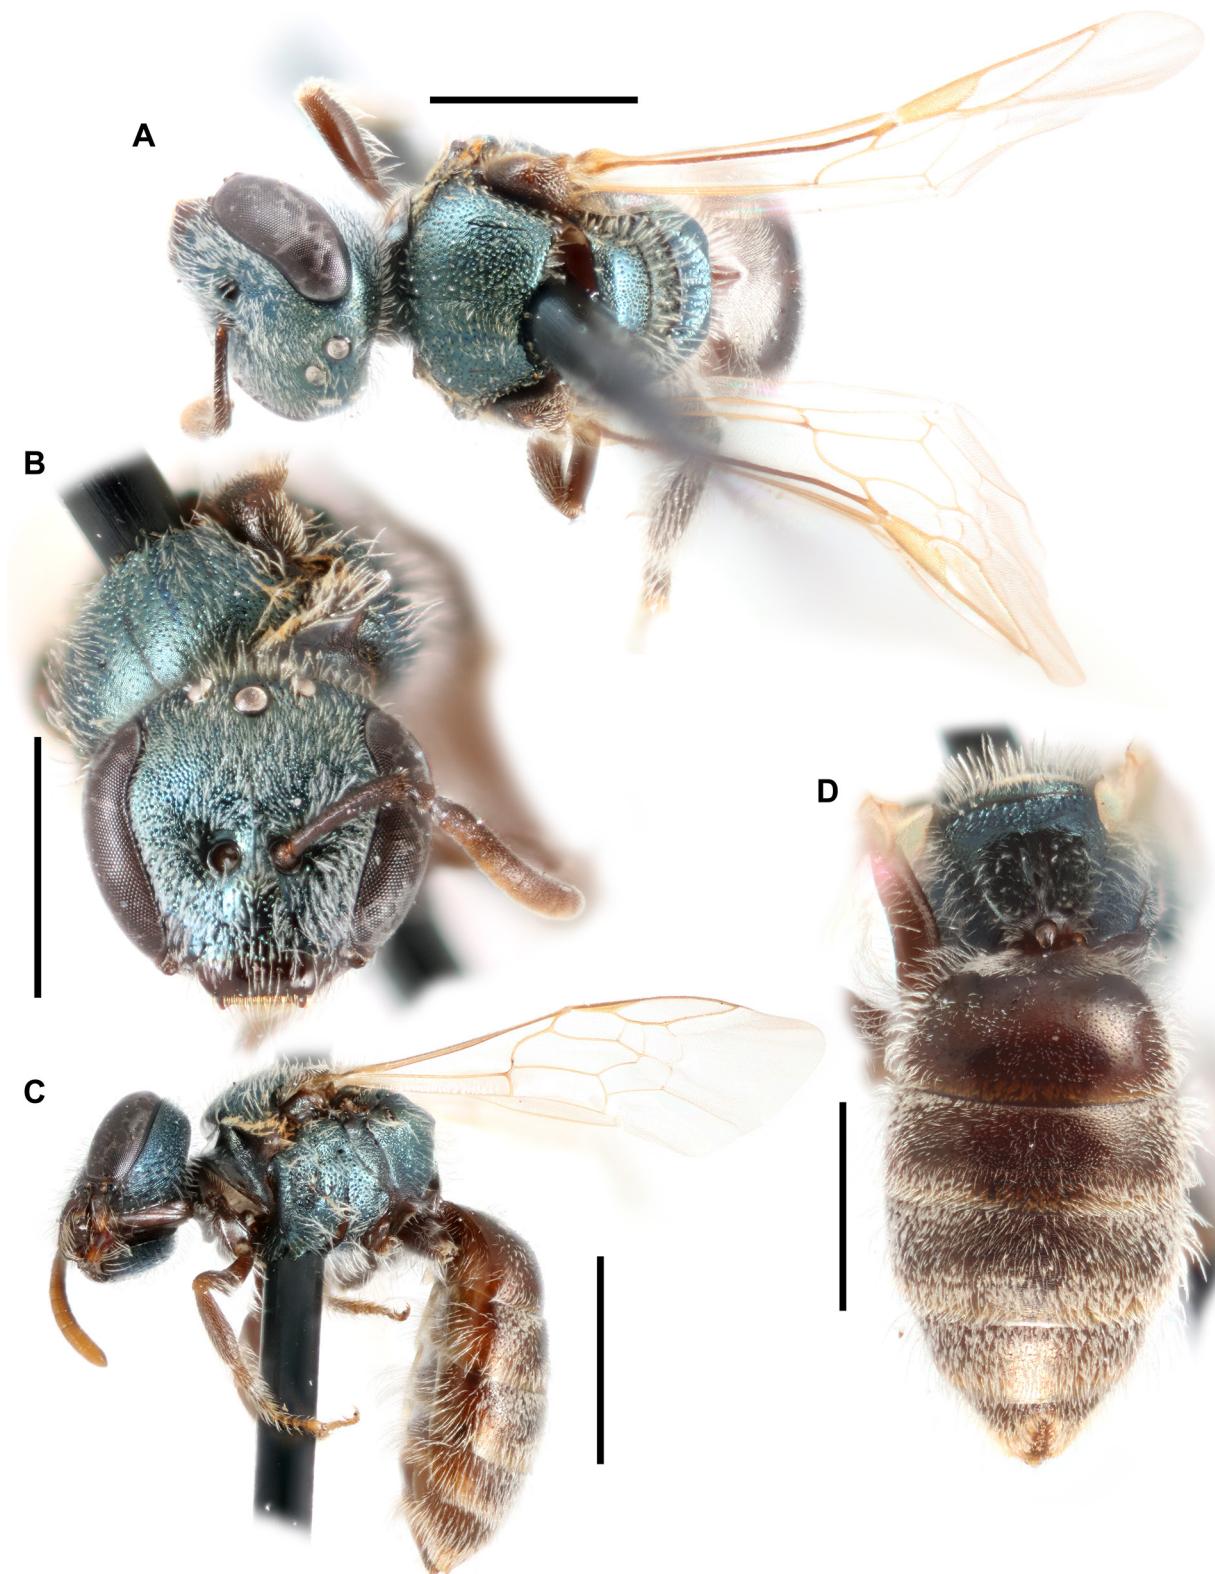

Fig. 9. *Lasioglossum (D.) coactus* (Cresson, 1872), ♀. **A.** Dorsal habitus. **B.** Face. **C.** Lateral habitus. **D.** Metasoma and propodeum. Scale bars = 1 mm.

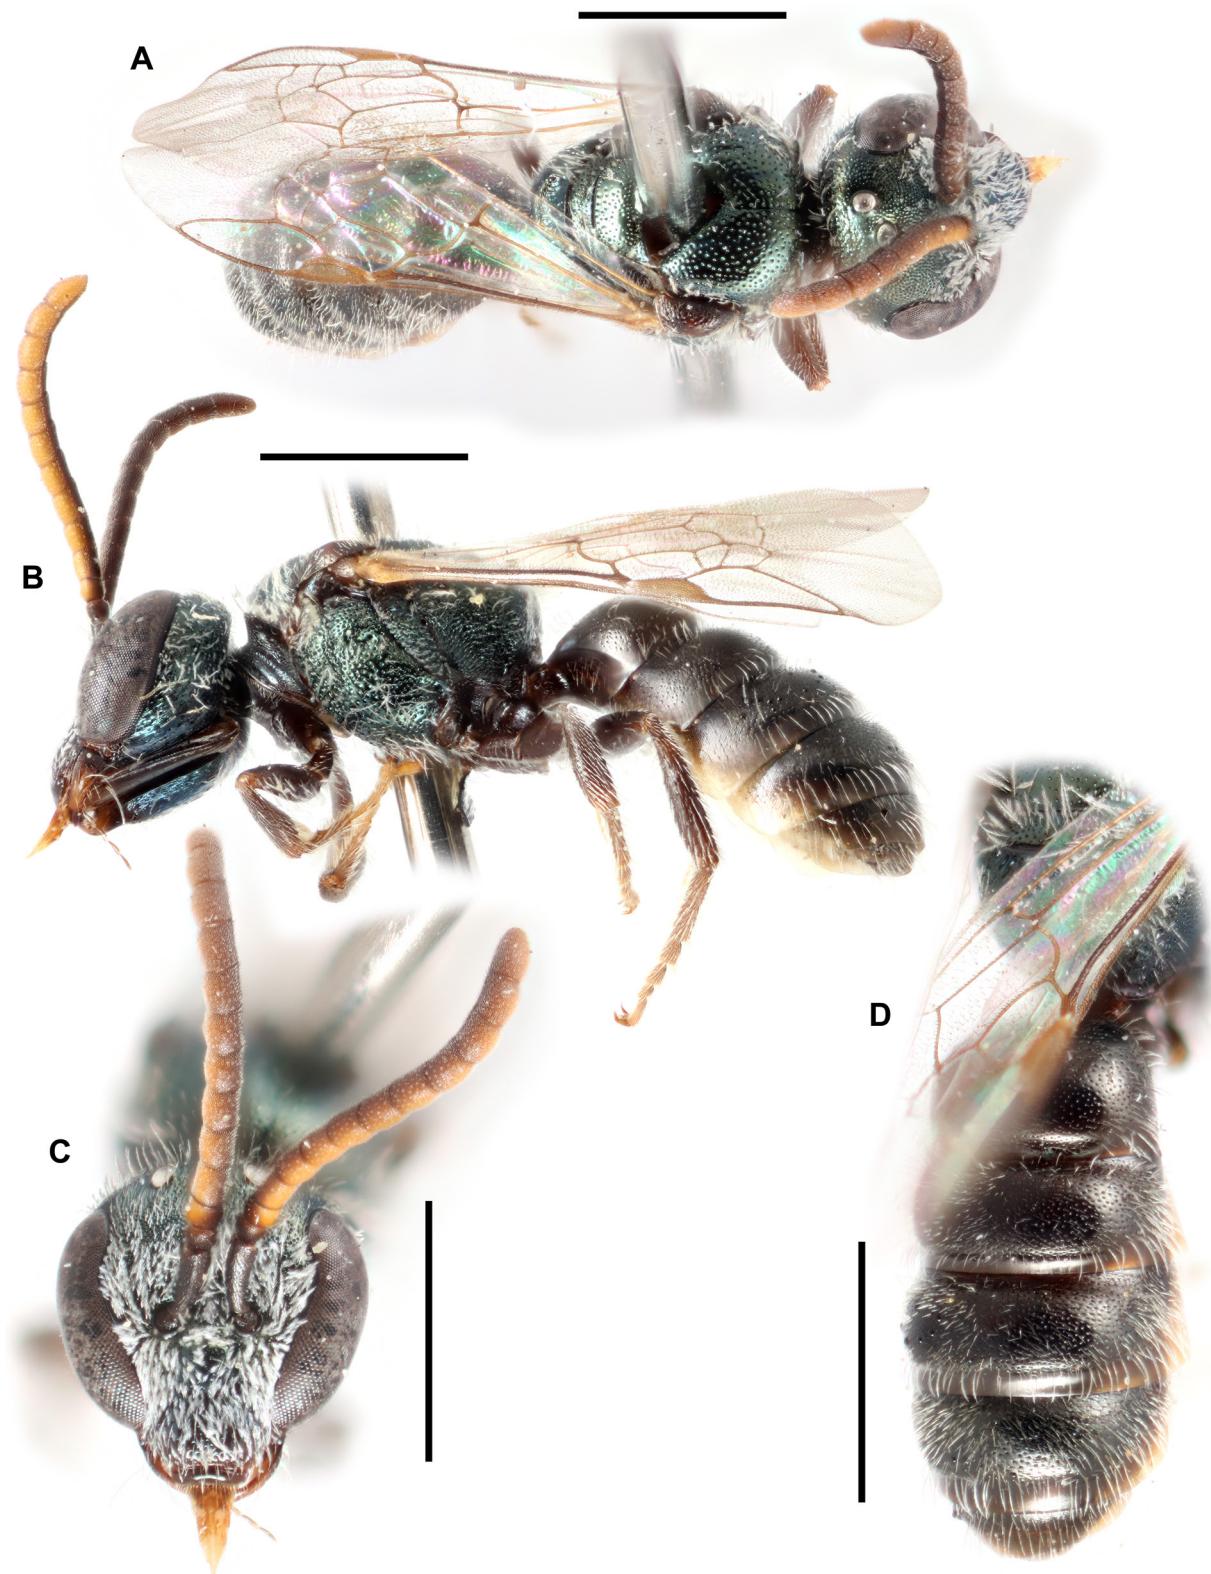

Fig. 10. *Lasioglossum (D.) coactus* (Cresson, 1872), ♂. **A.** Dorsal habitus. **B.** Lateral habitus. **C.** Face. **D.** Metasoma. Scale bars = 1 mm.

Etymology

The specific epithet ‘*coactus*’ could be either a Latin noun (compulsion, constraint) or a perfect participle (forced, compelled). Because Cresson (1872) did not specify the intended grammar, according to Article 31.2.2 of the *International Code of Zoological Nomenclature* (ICZN 1999), the epithet is treated as a noun and is therefore not declinable to ‘*coactum*’ in combination with ‘*Lasioglossum*’, as has been done in the past.

DNA barcodes

Eight confirmed sequences available, two haplotypes (BOLD process IDs: BWTWO1314-10, DLII051-06, LASNA016-08 (haplotype 1); DIAL1132-07, DLII307-07, DLII318-07, DLII338-07, DLII547-07 (haplotype 2)). Haplotype 1 is very similar to *L. carlinvillense*, and haplotype 2 is very similar to *L. tegulare*. There is a large amount of divergence within these sequences (3.36% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. carlinvillense* (0.15% minimum interspecific p-distance). No fixed nucleotide substitutions distinguish all *L. coactus* from all other Nearctic species of

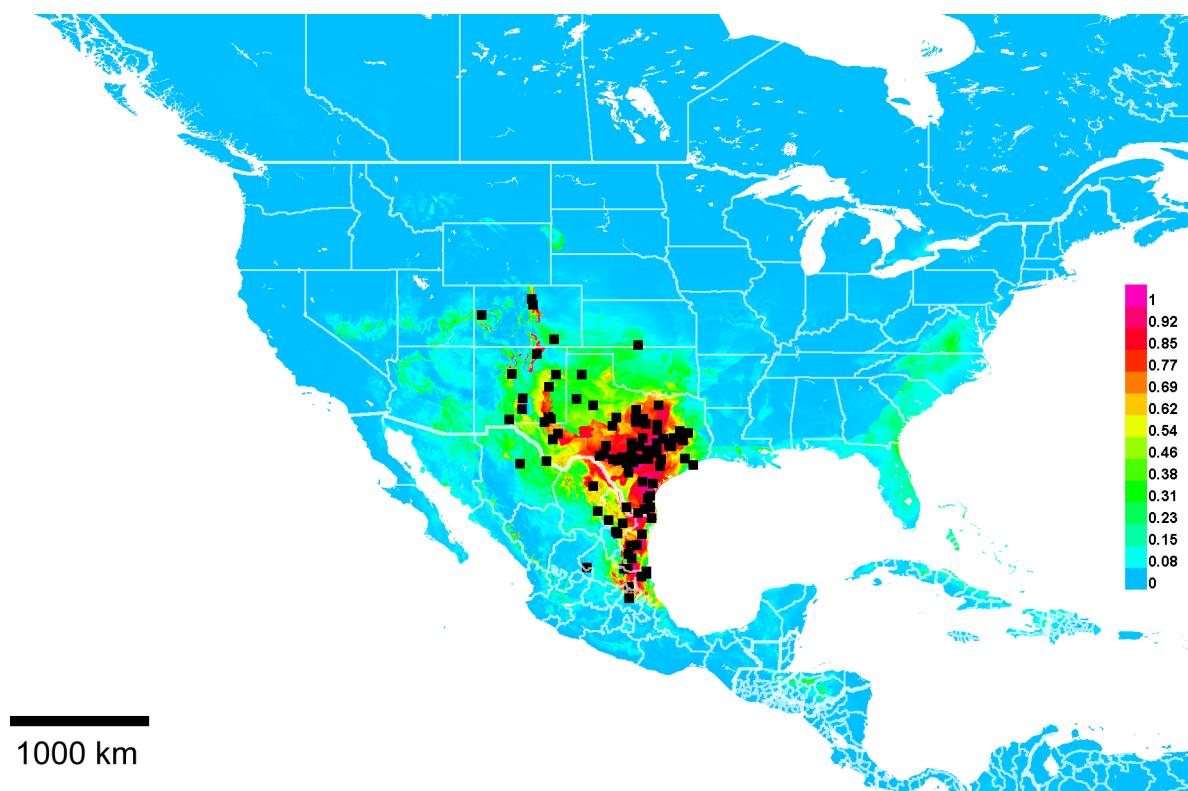

Fig. 11. Georeferenced collection records of *Lasioglossum (D.) coactus* (Cresson, 1872) (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

the *L. gemmatum* complex, but one fixed substitution distinguishes haplotype 1, and two fixed substitutions distinguish haplotype 2: 156(C) (haplotype 1); 429(G) and 441(C) (haplotype 2) ([Supp. file 2](#)).

***Lasioglossum (Dialictus) deludens* sp. nov.**

Figs 12–14, 76C, 78D, 102C

Dialictus deludens (nomen nudum) – De Luca *et al.* 2019: 4879.

Diagnosis

Females of *L. deludens* sp. nov. have the tegula relatively small (barely reaching posterior margin of mesoscutum in dorsal view if at all), translucent yellow-orange, impunctate, and with inner posterior margin straight; mesoscutum punctures smaller and finer in comparison to mesepisternum punctures, dense (IS < 1 PD) and becoming moderately sparse anteromedially and usually submedially (IS = 1–3 PD); mesoscutum usually becoming shiny posteriorly; metapostnotum shiny with strong anastomosing rugae; mesepisternum densely punctate (IS < 1 PD) and usually shiny; paraocular area with dense tomentum; and metasoma black to brown (rarely somewhat reddish, but never bright red-orange).

Females of *L. deludens* sp. nov. are most similar to those of *L. profundum* sp. nov., *L. rufodeludens* sp. nov., and some *L. diabolicum* sp. nov. Females of *L. profundum* have the tegula dark brown, mesoscutum punctures about as large and coarse as mesepisternum punctures, and mesepisternum imbricate. Females of *L. rufodeludens* have the mesoscutum and mesepisternum completely dull and metasoma red-orange. Females of *L. diabolicum* have the tegula with at least some punctures medially (may be difficult to see if the tegula is very pale yellow) and the mesoscutum punctures about as large and coarse as mesepisternum punctures.

Males of *L. deludens* sp. nov. have the same characters as for females, in addition to the face completely covered with dense appressed tomentum extending above eye emargination but not reaching median ocellus. They are most similar to those of *L. profundum* sp. nov. and *L. rufodeludens* sp. nov. Males of *L. profundum* have the tegula dark brown and, in direct comparison, the mesosoma and metasoma punctures are larger and coarser. Males of *L. rufodeludens* sp. nov. have the mesoscutum mostly or entirely tessellate and slightly more densely punctate (IS = 1–2 PD) and face with dense tomentum not extending above eye emargination.

An undescribed species unrelated to the *L. gemmatum* complex and occurring sympatrically with *L. deludens* sp. nov. is superficially similar in both sexes, but the tegula is small and ovoid and the propodeum lacks an oblique carina.

Etymology

The specific epithet ‘*deludens*’ is the Latin present participle of ‘*deludo*’ (deceive, dupe). It refers to this species’ frequent misidentification in the past. An appropriate translation would be the deceiving sweat bee.

Material examined

Description

Female

COLOURATION. Head and mesosoma blue to blue-green; clypeus apex black; labrum reddish brown; mandible orange with black base and red apex; flagellum dark reddish brown dorsally, light brown ventrally. Pronotal lobe dark reddish brown; legs reddish brown; tegula translucent orange; wing membrane hyaline, veins with subcosta dark brown, otherwise brown to pale amber. Metasoma dark reddish brown with rims of terga and sterna broadly translucent yellow.

PUBESCENCE. Body pile colour white. Tomentum dense on paraocular area, frons lower half, gena, pronotal collar and lobe, space between pronotal lobe and tegula, metanotum anterior margin, metepisternum, T2–T3 basolaterally, and T4 throughout; sparse on clypeus upper half, supraclypeal area, preepisternum, and mesepisternum. Mesoscutum pubescence thin to moderately plumose. Wing setae light and dark, short and dense. Acarinarial fan complete, sparse. T2 fringes sparse, T3 fringes sparse.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense in basal half ($IS < 1$ PD), large and irregularly sparse apically ($IS < 2$ PD); supraclypeal area shiny, with punctures dense ($IS \leq 1$ PD); paraocular area weakly imbricate around antenna socket, otherwise shiny, with punctures dense ($IS < 1$ PD); frons shiny, with punctures crowded ($IS = 0$ PD); vertex shiny, with punctures dense laterally ($IS < 1$ PD), fine and sparse medially ($IS = 1–3$ PD); gena shiny, with punctures dense ($IS \leq 1$ PD); postgena shiny, becoming imbricate posteriorly. Tegula punctures absent; mesoscutum tessellate, becoming shiny posterolaterally, with punctures dense ($IS < 1$ PD), becoming moderately sparse submedially and anteromedially ($IS = 1–2$ PD); scutellum tessellate, becoming shiny submedially, with punctures dense ($IS < 1$ PD); metapostnotum weakly imbricate, becoming tessellate posteriorly, with rugae strong, anastomosing, nearly reaching posterior margin; preepisternum shiny with crowded punctures ($IS = 0$ PD); hypoepimeron shiny, with punctures dense ($IS < 1$ PD); mesepisternum shiny, with punctures dense ($IS < 1$ PD); metepisternum ruguloso-lineate dorsally, ruguloso-punctate medially, tessellate ventrally; propodeum lateral surface tessellate, posterior surface tessellate. T1 anterior slope weakly coriarious, disc shiny, with punctures moderately dense ($IS = 1–2$ PD), impunctate in large subapicalateral boss and on rim medially; T2 disc shiny, with punctures moderately dense ($IS = 1–2$ PD), apical rim weakly coriarious, with punctures sparse ($IS = 1–3$ PD).

STRUCTURE. Face length/width ratio 0.81 (± 0.01 SD); clypeus apicolateral denticles rounded knobs; gena/eye width ratio 0.9 (± 0.06 SD). Pronotal angle slightly obtuse, nearly right-angled; intertegular span 0.84 (± 0.03 SD) mm; mesoscutum length/width ratio 0.85 (± 0.02 SD); mesoscutum/scutellum length ratio 2.86 (± 0.16 SD); scutellum/metanotum length ratio 1.58 (± 0.1 SD); metanotum/metapostnotum length ratio 0.68 (± 0.09 SD); forewing with 3 submarginal cells; tegula enlarged, reaching posterior margin of mesoscutum; inner margin straight; tegula length 0.37 (± 0.03 SD) mm, width 0.19 (± 0.02 SD)

mm; propodeum lateral carinae not reaching dorsal margin; oblique carina strong, straight. T2 depressed apical rim less than 50% of tergum. (n = 11)

VARIATION. Various parts of the integument including the clypeus apical margin, labrum, flagellum ventral surface, pronotal lobe, and leg joints can vary from black to orange. The metasoma can vary from black to reddish brown. The tegula is rarely opaque brown but still maintains an orange tint distinct from *L. profundum* sp. nov. (this may be due to liquid accumulating and drying under the tegula). The mesoscutum and mesepisternum are sometimes entirely dull, the mesoscutum is sometimes densely punctate submedially (IS \leq 1 PD), and the metasomal terga can be shiny or coriarious.

Male

COLOURATION. Head and mesosoma blue to blue-green; clypeus apex reddish brown; labrum reddish brown to orange; mandible orange with black base and red apex; flagellum reddish brown dorsally, orange ventrally. Pronotal lobe dark reddish brown; legs reddish brown with femur-tibia joints and tarsi light brown to orange; tegula orange or reddish brown; wing membrane hyaline, veins with subcosta dark brown, otherwise brown to pale amber. Metasoma black or dark reddish brown with depressed apical rims of terga and sterna lighter reddish brown, downcurved lateral areas of terga becoming translucent yellow.

PUBESCENCE. Body pile colour white. Tomentum dense on face below median ocellus, gena, pronotal angle and lobe, and space between pronotal lobe and tegula; sparse on margins of mesoscutum, episterna, and T2–T3 basolaterally. Mesoscutum pubescence simple to moderately plumose. Wing setae light with dark intermixed apically, long and sparse. Sterna pubescence short (0.5–1.5 OD), moderately plumose, sparse.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense (IS < 1 PD); supraclypeal area shiny, with punctures dense (IS \leq 1 PD); paraocular area shiny, with punctures dense (IS < 1 PD); frons shiny, with punctures crowded (IS = 0 PD); vertex shiny, with punctures dense laterally (IS < 1 PD), moderately sparse medially (IS = 1–2 PD); gena shiny, with punctures dense (IS \leq 1 PD); postgena shiny to weakly imbricate. Tegula punctures absent; mesoscutum shiny, with punctures moderately sparse (IS = 1–2 PD), becoming dense marginally and on median line (IS \leq 1 PD); scutellum shiny, with punctures dense (IS \leq 1 PD); metanotum shiny to weakly imbricate and densely punctate (IS < 1 PD); metapostnotum shiny to imbricate, with rugae strong, anastomosing, reaching or nearly reaching posterior margin; preepisternum shiny with crowded punctures (IS = 0 PD); hypoepimeron shiny, with punctures dense (IS < 1 PD); mesepisternum shiny, with punctures dense (IS < 1 PD); metepisternum ruguloso-lineate dorsally, areolate ventrally; propodeum lateral surface shiny to imbricate, with punctures dense (IS \leq 1 PD) to crowded (IS = 0 PD), posterior surface shiny with dense punctures (IS < 1 PD). T1 anterior slope shiny, disc shiny, with punctures moderately dense (IS = 1–2 PD), sparse in small subapicolateral boss (IS = 2–6 PD) and absent on rim medially; T2 disc shiny, with punctures moderately dense (IS = 1–2 PD), apical rim shiny, with punctures absent.

STRUCTURE. Face length/width ratio 0.86 (± 0.03 SD); gena/eye width ratio 0.77 (± 0.09 SD). Pronotal angle obtuse; intertegular span 0.71 (± 0.07 SD) mm; mesoscutum length/width ratio 0.89 (± 0.03 SD); mesoscutum/scutellum length ratio 2.67 (± 0.14 SD); scutellum/metanotum length ratio 1.87 (± 0.17 SD); metanotum/metapostnotum length ratio 0.71 (± 0.07 SD); forewing with 3 submarginal cells; tegula enlarged, reaching or nearly reaching posterior margin of mesoscutum in dorsal view; inner margin weakly concave; tegula length 0.35 (± 0.03 SD) mm, width 0.19 (± 0.01 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina absent. (n = 10)

GENITALIA. As in Fig. 76C. Gonocoxite about 1.3 times as broad as gonostylus. Gonostylus rounded on outer margin with no concavities, with sparse long setae dorsally and short setae along inner margin. Penis valves divergent apically, with short sparse setae dorsolaterally in basal half. Retorse lobe rounded, about 2.5 times as long as broad, with sparse short setae apically.

VARIATION. The mesoscutum and scutellum punctures can vary from dense ($IS \leq 1.5$ PD) to sparse ($IS = 1\text{--}3$ PD), the metapostnotum can vary from mostly shiny to mostly imbricate, and the propodeum lateral face can vary from shiny and distinctly punctate to imbricate and obscurely punctate.

Range

Sonoran, Chihuahuan, and Mojave Deserts (Fig. 14).

In addition to the above records, some of the floral hosts reported for *L. perparvum* in Moure & Hurd (1987) are likely attributable to *L. deludens* sp. nov.

DNA barcodes

Seventeen confirmed sequences available (BOLD process IDs: DLII753-07, DLII763-07, DLII771-07, DLII786-07, DLII793-07, DLII795-07, DLII802-07, DLII806-07, DLII809-07, DLII987-07, DLII1075-07, DLII1077-07, DLII1122-07, DIAL1099-07, DIAL1129-07, DIAL1174-07, DIAL1430-09). There is a moderate amount of divergence within these sequences (0.76% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. profundum* sp. nov. (0.95% minimum interspecific p-distance). Two fixed nucleotide substitutions distinguish *L. deludens* sp. nov. from all other Nearctic species of the *L. gemmatum* complex: 346(C) and 471(C) ([Supp. file 2](#)).

Comments

Very common. In the Sonoran Desert, *L. deludens* sp. nov. is one of the two most abundant species of *L. (Dialictus)* along with *L. microlepoide*s (Ellis, 1914). These two species are about equally abundant and together often comprise 50% or more of collections of *L. (Dialictus)* in this area. Many thousands of additional specimens are known to exist but were not examined in this study.

Most specimens determined as *L. perparvum* in various collections prior to this work were actually *L. deludens* sp. nov. This could be due to an initial misidentification which was then propagated by later workers. After the error was discovered, *L. deludens* was usually referred to as “*L. aff. perparvum*” or “*L. nr. perparvum*”. Alternatively, *L. deludens* could have been called “*L. nr. perparvum*” at first, and later workers disregarded the “near”. Approximate dates of identification (especially by George Eickwort, who determined many specimens) would be necessary to distinguish these scenarios. Morphology and DNA barcodes easily distinguish *L. deludens* and *L. perparvum*.

Lasioglossum (Dialictus) diabolicum sp. nov.

[urn:lsid:zoobank.org:act:2E554E7E-C8BF-49C4-AC08-2EB5886A18E3](https://lsid.zoobank.org/act:2E554E7E-C8BF-49C4-AC08-2EB5886A18E3)

Figs 15–17, 76D, 87B, 97B, 98A, 99B, 100A, 117B, 119B, 120B

Diagnosis

Females of *L. diabolicum* sp. nov. have the tegula relatively small (barely reaching posterior margin of mesoscutum in dorsal view if at all), inner posterior margin straight, with a blunt posterior angle or small bump, and mediolateral area usually somewhat sparsely punctate (IS ≥ 1 PD); mesepisternum punctures usually larger and slightly sparser than hypoepimeron punctures; mesoscutum and mesepisternum sometimes shiny; metapostnotum usually dull with anastomosing rugae; mesoscutum with dense erect

pubescence (each seta less than its length from the next nearest one with intervening setae short but having measurable length up to 0.5 OD); and tegula and metasoma often red-orange.

Females of *L. diabolicum* sp. nov. are most similar to those of *L. deludens* sp. nov., *L. ellisiae*, and *L. perparvum*. Females of *L. deludens* have the tegula impunctate medially, mesoscutum punctures finer in comparison to mesepisternum, and metasoma black to brown. Females of *L. ellisiae* have the mesepisternum punctures as fine and dense as on hypopimeron, tegula slightly larger (reaching posterior margin of mesoscutum in dorsal view) with inner posterior margin sinuous, and metapostnotum usually shiny with subparallel rugae. In red-tailed forms, *L. diabolicum* usually have the basal half of T1 dark brown, while in *L. ellisiae* it is entirely red. Females of *L. perparvum* have the mesoscutum with much shorter, sparser pubescence (each long erect seta about its length from the next nearest one, with intervening setae no more than stubble), mesoscutum and mesepisternum dull, and metasoma dark brown to black.

Males of *L. diabolicum* sp. nov. have the tegula relatively small (as in the female); mesoscutum usually shiny and coarsely and moderately sparsely punctate (IS = 1–2 PD); mesepisternum usually densely punctate (IS ≤ 1 PD); T1–T2 with discs finely and moderately sparsely punctate (IS = 1–2 PD) and apical rims impunctate; and mesoscutum with numerous long plumose setae (as in the female).

Males of *L. diabolicum* sp. nov. are most similar to those of *L. ellisiae*, *L. helianthi*, and *L. perparvum*. Males of *L. ellisiae* have the mesoscutum more evenly and densely punctate (IS ≤ 1 PD between parapsidal lines) and disc of T2 sometimes more deeply and densely punctate in basal half (IS ≤ 1 PD). Males of *L. helianthi* have the mesoscutum entirely densely punctate (IS ≤ 1 PD) and T1–T2 more deeply and densely punctate (IS ≤ 1 PD) including apical rims in part. Males of *L. perparvum* have the mesoscutum usually tessellate, more finely and densely punctate (IS ≤ 1 PD), and with sparse erect setae (with gaps 0.5 OD or more visible in lateral view) appearing simple at 40 × magnification.

Some other species in the *L. stictaspis* species complex can also be very similar in both sexes, but have the tegula slightly larger (reaching or exceeding posterior margin of mesoscutum in dorsal view) and inner posterior margin concave with a distinct, rounded posterior projection.

Etymology

The specific epithet ‘*diabolicum*’ is a Latin adjective meaning ‘devilish’. It is a reference to this species’ close relationship to *L. angelicum* sp. nov. and its variable morphology and DNA barcodes which make delimitation and identification very difficult.

Description

Female

COLOURATION. Head and mesosoma olive green; clypeus apex black; labrum reddish brown; mandible orange with black base and red apex; flagellum dark brown dorsally, lighter brown ventrally. Pronotal lobe dark brown; legs brown; tegula brown; wing membrane lightly infuscated, veins with subcosta dark brown, otherwise light brown. Metasoma black to reddish brown with rims of terga and sterna narrowly translucent yellow.

PUBESCENCE. Body pile colour white to pale yellow. Tomentum dense on pronotal angle and lobe, space between pronotal lobe and tegula, and T2–T3 basolaterally; sparse on gena, metepisternum, and T4. Mesoscutum pubescence moderately to densely plumose. Wing setae dark, short and dense. Acinarial fan complete, dense. T2 fringes sparse, T3 fringes dense.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense in basal third ($IS < 1$ PD), large and irregularly spaced apically ($IS < 2$ PD); supraclypeal area shiny, with punctures dense ($IS \leq 1$ PD); paraocular area weakly imbricate around antenna socket, otherwise shiny, with punctures crowded ($IS = 0$ PD), irregularly sparser around antenna socket ($IS < 2$ PD); frons reticulate, with punctures crowded ($IS = 0$ PD); vertex shiny, with punctures crowded laterally ($IS = 0$ PD), moderately sparse and obscure medially ($IS = 1–2$ PD); gena shiny, becoming lineolate posteriorly and ventrally, with punctures fine, moderately dense ($IS = 1–2$ PD); postgena lineolate. Tegula punctures dense ($IS < 1$ PD), becoming sparse medially ($IS = 1–3$ PD); mesoscutum tessellate, with punctures dense ($IS < 1$ PD), becoming moderately sparse anteromedially ($IS = 1–2$ PD); scutellum shiny, with punctures dense ($IS \leq 1$ PD); metapostnotum finely reticulate, with rugae strong, anastomosing, reaching posterior margin; preepisternum ruguloso-punctate; hypoepimeron shiny, with punctures crowded ($IS = 0$ PD); mesepisternum imbricate, with punctures dense ($IS < 1$ PD); metepisternum finely rugulose; propodeum lateral surface tessellate, posterior surface tessellate. T1 anterior slope coriarious, disc shiny, with punctures fine, moderately sparse ($IS = 1–3$ PD), absent in large subapicalateral boss and on rim; T2 disc shiny, with punctures fine, moderately dense ($IS = 1–2$ PD), apical rim weakly coriarious, with punctures minute, sparse ($IS = 2–4$ PD), obscure.

STRUCTURE. Face length/width ratio 0.83 (± 0.02 SD); clypeus apicolateral denticles low rounded knobs; gena/eye width ratio 0.88 (± 0.07 SD). Pronotal angle obtuse; intertegular span 0.93 (± 0.08 SD) mm; mesoscutum length/width ratio 0.86 (± 0.04 SD); mesoscutum/scutellum length ratio 2.83 (± 0.25 SD); scutellum/metanotum length ratio 1.61 (± 0.16 SD); metanotum/metapostnotum length ratio 0.66 (± 0.06 SD); forewing with 3 submarginal cells; tegula enlarged, reaching posterior margin of mesoscutum in dorsal view; inner posterior margin straight; tegula length 0.41 (± 0.03 SD) mm, width 0.23 (± 0.02 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina strong, straight. T2 depressed apical rim less than 50% of tergum. (n = 10)

VARIATION. The tegula punctures can vary from sparse ($IS = 1–3$ PD) to entirely dense ($IS < 1$ PD), the mesoscutum punctures can vary from moderately sparse ($IS = 1–2$ PD) to dense ($IS < 1$ PD), the mesoscutum and mesepisternum are usually dull and strongly tessellate or imbricate but can be somewhat shiny; the metapostnotum can vary from shiny with coarse rugae to dull with fine rugae, and the tegula and metasoma can vary from dark brown to bright orange.

Male

COLOURATION. Head and mesosoma blue to blue-green; clypeus apex black; labrum black; mandible orange with black base and red apex; flagellum dark reddish brown dorsally, light brown ventrally. Pronotal lobe dark reddish brown; legs dark reddish brown with femur-tibia joints and tarsi becoming light brown; tegula reddish brown; wing membrane hyaline, veins dark brown. Metasoma black with

depressed apical rims of terga and sterna reddish brown, downcurved lateral areas of terga becoming translucent brown.

PUBESCENCE. Body pile colour white. Tomentum dense on face below eye emargination, pronotal collar and lobe, and space between pronotal lobe and tegula; very sparse on gena, preepisternum, and T2–T3 basolaterally. Mesoscutum pubescence simple to moderately plumose. Wing setae dark, short and dense. Sterna pubescence short (~1 OD), moderately plumose, sparse.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense ($IS < 1$ PD); supraclypeal area shiny to weakly imbricate, with punctures dense ($IS < 1$ PD) with impunctate median line 1 PD or more wide; paraocular area shiny, with punctures dense ($IS < 1$ PD); frons reticulate, with punctures crowded ($IS = 0$ PD); vertex shiny, with punctures dense laterally ($IS < 1$ PD), moderately dense medially ($IS = 1–2$ PD); gena shiny, with punctures fine, moderately sparse ($IS = 1–2$ PD); postgena shiny to weakly lineate. Tegula punctures dense ($IS < 1$ PD), becoming fine and moderately sparse laterally ($IS = 1–2$ PD); mesoscutum shiny, becoming weakly tessellate anteromedially, with punctures dense ($IS \leq 1.5$ PD), becoming crowded marginally ($IS = 0$ PD); scutellum shiny, with punctures dense ($IS \leq 1.5$ PD), becoming crowded marginally ($IS = 0$ PD); metanotum shiny to weakly imbricate and densely punctate ($IS \leq 1$ PD); metapostnotum shiny to finely reticulate, with rugae strong, anastomosing, reaching posterior margin; preepisternum areolate; hypoepimeron shiny, with punctures crowded ($IS = 0$ PD); mesepisternum shiny, with punctures dense ($IS < 1$ PD); metepisternum areolate; propodeum lateral surface areolate to rugulose, with punctures crowded ($IS = 0$ PD), posterior surface shiny with crowded punctures ($IS = 0$ PD), becoming areolate laterally. T1 anterior slope shiny, disc shiny, with punctures fine, moderately sparse ($IS = 1–3$ PD), absent in small subapicolateral boss and on rim; T2 disc shiny, with punctures fine, moderately sparse ($IS = 1–2$ PD), apical rim shiny, with punctures absent.

STRUCTURE. Face length/width ratio 0.85 (± 0.03 SD); gena/eye width ratio 0.67 (± 0.06 SD). Pronotal angle obtuse; intertegular span 0.68 (± 0.05 SD) mm; mesoscutum length/width ratio 0.95 (± 0.03 SD); mesoscutum/scutellum length ratio 2.68 (± 0.09 SD); scutellum/metanotum length ratio 1.84 (± 0.13 SD); metanotum/metapostnotum length ratio 0.7 (± 0.07 SD); forewing with 3 submarginal cells; tegula enlarged, nearly reaching posterior margin of mesoscutum in dorsal view; inner posterior margin weakly concave; tegula length 0.35 (± 0.02 SD) mm, width 0.19 (± 0.01 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina absent. ($n = 10$)

GENITALIA. As in Fig. 76D. Gonocoxite nearly 2 times as broad as gonostylus. Gonostylus rounded, slightly concave on outer margin, with sparse long setae dorsally and short setae along inner margin. Penis valves parallel. Retrorse lobe rounded, about 3 times as long as broad, with sparse short setae on basal half and apical margin.

VARIATION. The tegula can sometimes be entirely densely punctate ($IS < 1$ PD), the mesoscutum punctuation can vary from mostly dense ($IS \leq 1$ PD) to sparse ($IS = 1–3$ PD), the metapostnotum can vary from shiny with strong rugae to dull with fine rugae, and the head and mesosoma can vary from blue to golden-green.

Range

Western Colorado, Utah, and southern Nevada, south along the Colorado River valley and east along the Gila River valley to Phoenix, Arizona (Fig. 17).

DNA barcodes

Eleven confirmed sequences available, three haplotypes (BOLD process IDs: BHHT023-09, DLII890-07, DLII1067-07, DLII1099-07, DLII1232-08, DLII1233-08, DLII1694-09, DLII1696-09 (haplotype 1); DLII940-07, DLII1677-09 (haplotype 2); DLIII124-18 (haplotype 3)). There is a large amount of divergence within these sequences (2.29% maximum intraspecific p-distance). They are closest in terms of p-distance to the *L. stictaspis* species complex (0% minimum interspecific p-distance). No fixed nucleotide substitutions distinguish all *L. diabolicum* sp. nov. from all other Nearctic species of the *L. gemmatum* complex, but three fixed substitutions distinguish haplotype 1: 33(G), 111(C), and 588(C) ([Supp. file 2](#)).

Comments

Some specimens with the tegula slightly larger and more densely punctate than usual are extremely difficult to separate from *L. stictaspis*, and are therefore excluded from paratype status. These specimens may be hybrids or a separate, cryptic species. The barcoded haplotype 3 specimen is one such specimen, but the haplotype 2 specimens are morphologically indistinguishable from haplotype 1 (which includes the holotype). It is thought that haplotype 1 is the ‘natural’ barcode sequence of *L. diabolicum* sp. nov., and the additional haplotypes are a result of introgression or incomplete lineage sorting.

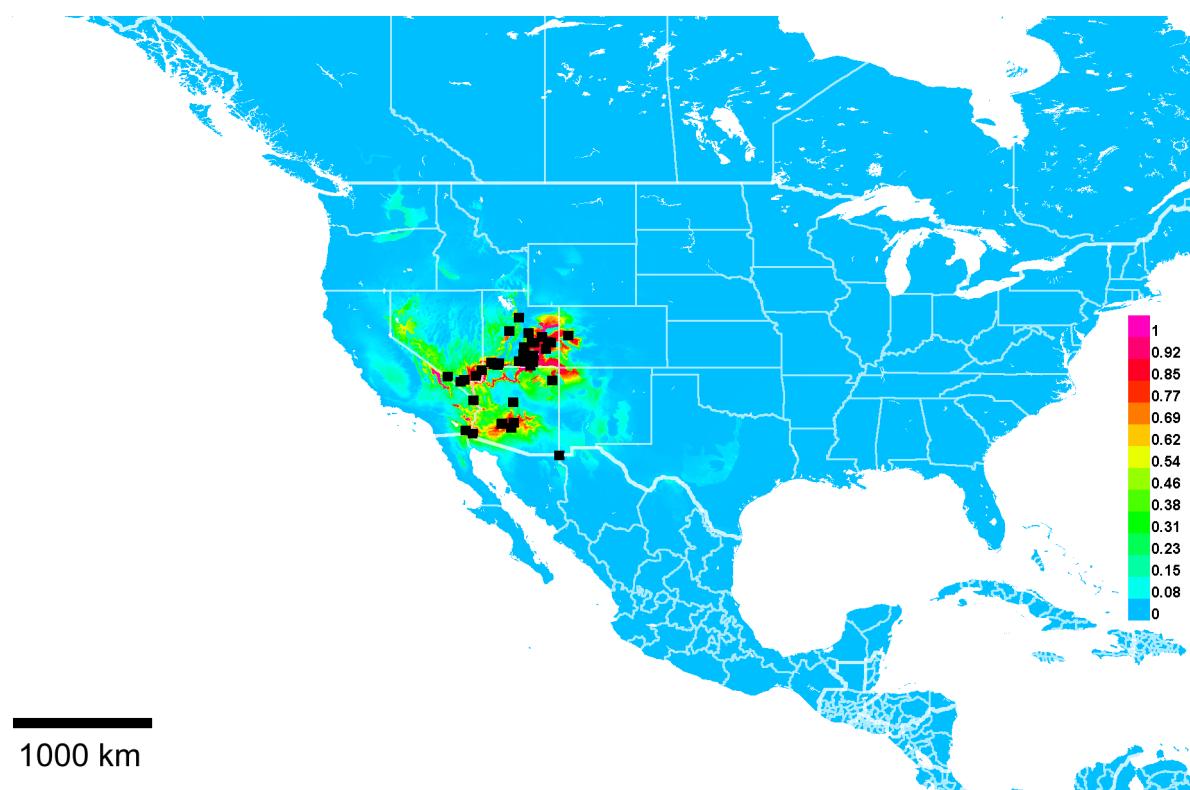

Fig. 17. Georeferenced collection records of *Lasioglossum (D.) diabolicum* sp. nov. (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

Lasioglossum (Dialictus) ellisiae – Gibbs 2009a: 18 (resurrection from synonymy, revision); 2010: 37, 45 (key to species), 120 (redescription); 2011: 25, 32 (key to species), 88 (review). — Wolf & Ascher 2009: 143 (checklist). — Gibbs *et al.* 2013: 80 (checklist). — Dibble *et al.* 2017: 13 (checklist). — Kilpatrick *et al.* 2020: 54 (checklist).

Diagnosis

Females of *L. ellisiae* have the tegula somewhat small (reaching and sometimes slightly exceeding posterior margin of mesoscutum in dorsal view), relatively sparsely punctate laterally at midlength (at least IS = 1 PD, up to IS = 1–3 PD), and inner posterior margin weakly concave, with a gentle S-shaped curve coming to a narrow rounded point posteriorly; mesepisternum punctures distinct, round, and about as fine and dense as those of hypoepimeron; metapostnotum shiny with coarse rugae reaching posterior margin; mesoscutum and mesepisternum usually shiny or with weak microsculpture; T1 anterior slope coriarious; T3 without subapical band of tomentum (rarely with some sparse tomentum apicolaterally); and tegula and metasoma sometimes red-orange.

Females of *L. ellisiae* are most similar to those of *L. diabolicum* sp. nov., *L. gaudiale*, *L. indagator* sp. nov., and *L. tegulare*. Females of *L. diabolicum* have the tegula slightly smaller (often not reaching posterior margin of mesoscutum in dorsal view) with inner posterior margin usually straight and metapostnotum usually dulled by strong microsculpture. Females of *L. gaudiale* have the T1 anterior slope shiny with microsculpture absent or very weak and the tegula inner posterior margin more strongly concave. Females of *L. indagator* have the metapostnotal rugae usually not reaching posterior margin and more extensive tomentum on the mesoscutum lateral and posterior margins, metanotum, and pleura. Females of *L. tegulare* have the mesoscutum and mesepisternum entirely dull with strong microsculpture and mesepisternum with crowded punctures (IS = 0 PD) some of which are not distinctly round. Some other species in the *L. stictaspis* species complex (particularly *L. stictaspis* s. str.) can also be very similar, but have the mesepisternum punctures larger and slightly sparser than those of hypoepimeron, mesoscutum more irregularly and sparsely punctate (as in *L. diabolicum*), tegula inner posterior margin usually more strongly concave and usually more densely punctate (IS ≤ 1 PD), metapostnotum usually dull with fine rugae, and T3 usually with dense and complete subapical band of tomentum.

Males of *L. ellisiae* have the tegula somewhat small (as in the female); metapostnotum usually shiny with strong subparallel rugae; mesoscutum between parapsidal lines uniformly densely punctate (IS ≤ 1 PD); and discs of T2–T3 becoming more sparsely punctate on premarginal line, not contrasting with impunctate apical rims (punctures in basal half of T2–T3 may be deep and dense (IS ≤ 1 PD) or fine and moderately sparse (IS = 1–2 PD)).

Males of *L. ellisiae* are most similar to those of *L. diabolicum* sp. nov., *L. lepidii*, *L. puteulanum*, and *L. tegulare*. All of these species have the mesoscutum more irregularly and slightly more sparsely punctate between the parapsidal lines (some IS < 1 PD and some IS = 1–2 PD). Males of *L. diabolicum* and *L. lepidii* have the disc of T2 uniformly finely and moderately sparsely punctate (IS = 1–2 PD). In direct comparison, males of *L. lepidii* also have the facial tomentum denser and more tightly appressed (more completely obscuring the surface underneath) and the mesothoracic spiracle more deeply impressed. Males of *L. puteulanum* and *L. tegulare* have the disc of T2 uniformly deeply and densely punctate (IS ≤ 1 PD) including the premarginal line. Some other species in the *L. stictaspis* species complex can also be very similar, but have the tegula slightly larger, with inner posterior margin more strongly concave, and more often entirely densely punctate (IS < 1 PD) and mesoscutum more irregularly and sparsely punctate (as above).

Eymology

Sandhouse (1924) dedicated this species to her fellow bee taxonomist Marion Durbin Ellis.

DNA barcodes

Nineteen confirmed sequences available (BOLD process IDs: BEECB221-07, BOWGF1482-10, BWTWO897-10, BWTWO899-10, BWTWO902-10, DIAL476-06, DIAL888-06, DIAL918-06, DIAL1089-06, DLII031-06, DLII1522-09, DLII1527-09, DLII1559-09, DLII1566-09, DLII1586-09, DLII1590-09, DLIII026-09, DLIII122-18, NCBEE387-21). There is a moderate amount of divergence

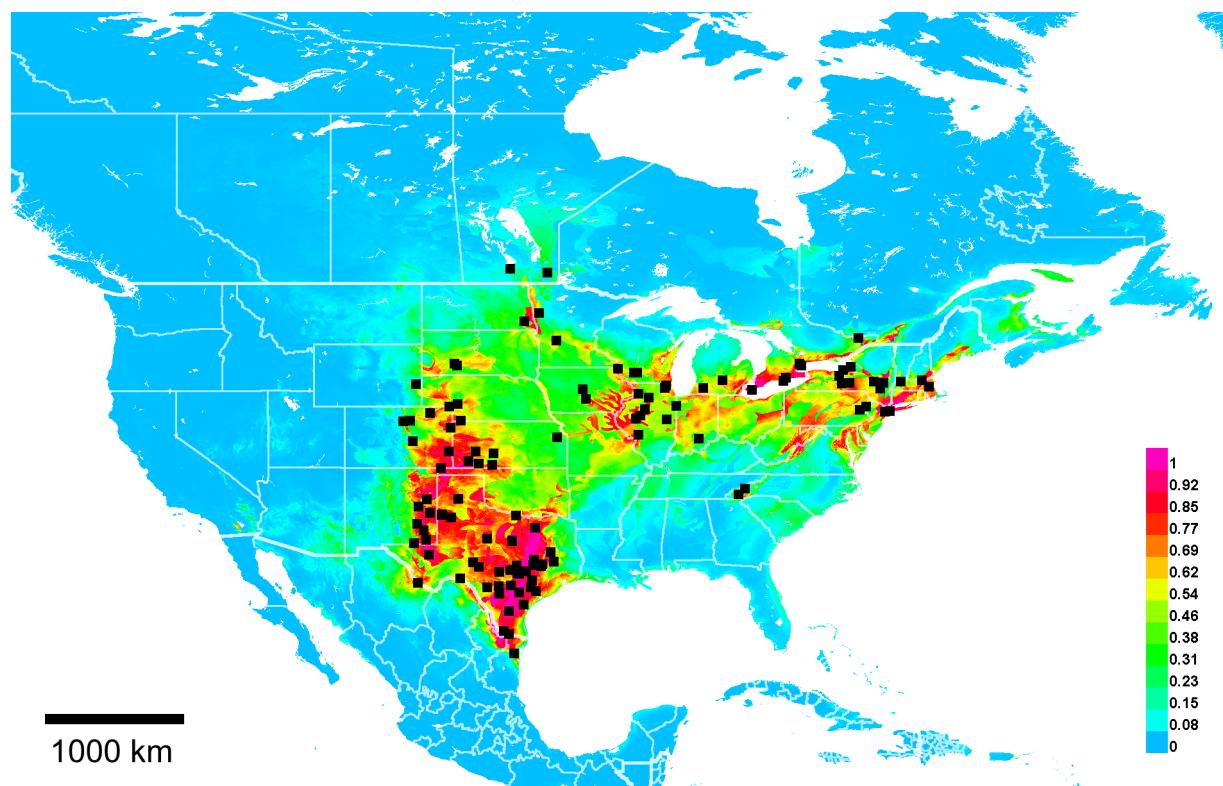

Fig. 20. Georeferenced collection records of *Lasioglossum (D.) ellisiae* (Sandhouse, 1924) (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

within these sequences (0.76% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. helianthi* (1.22% minimum interspecific p-distance). Two fixed nucleotide substitutions distinguish *L. ellisiae* from all other Nearctic species of the *L. gemmatum* complex: 312(A) and 573(C) ([Supp. file 2](#)).

Comments

Specimens of *L. ellisiae* from the southwestern parts of its range usually have the tegula and metasoma red-orange and have been considered a separate species, *L. hunteri*, in the past. However, the geographical boundaries of the dark forms and red-tailed forms are very fuzzy. Dark specimens of *L. ellisiae* are known from New Mexico and Colorado, and red-tailed specimens have been found as far north as Minnesota and Manitoba. No other morphological features can distinguish the two forms; if colour is disregarded, the holotype of *L. hunteri* is a typical *L. ellisiae*. An apparent distribution gap between eastern and western specimens (Fig. 20) is likely due to undersampling in eastern South Dakota, eastern Nebraska, eastern Kansas, Oklahoma, and Missouri. DNA barcodes from across the range of *L. ellisiae*, including red-tailed specimens from Texas and Minnesota, are indistinguishable. No line of evidence can support the hypothesis that *L. hunteri* is a distinct species.

Four unusual red-tailed specimens from southern Texas have the metapostnotum completely dull, smooth, and lacking rugae, even fine ones, in the apical 75%, but otherwise resemble typical *L. ellisiae*. The identification of these specimens is somewhat uncertain. They are tentatively included in *L. ellisiae* as the closest available match and because there is no additional evidence to support consideration of these specimens as a new species.

***Lasioglossum (Dialictus) eremum* sp. nov.**

[urn:lsid:zoobank.org:act:76F04F95-0D86-42FF-A596-C7415D9BB1FF](https://doi.org/10.1545/ejt.2023.0001)

Figs 21–23, 94B

Diagnosis

Females of *L. eremum* sp. nov. have the tegula relatively small (exceeding posterior margin of mesoscutum in dorsal view by about a seta's breadth if at all), with inner posterior margin straight or very weakly concave, and usually moderately sparsely punctate laterally at midlength (IS = 1–2 PD); metapostnotum rugose due to very strong anastomosing rugae reaching posterior margin; postgena smooth, at most weakly lineolate; mesoscutum and mesepisternum mostly shiny (mesoscutum becoming tessellate anteromedially and mesepisternum sometimes dull dorsally); T1 anterior slope coriarious; and apical rims of T1–T2 distinctly punctate with punctuation similar to discs (sometimes slightly sparser).

Females of *L. eremum* sp. nov. are most similar to those of *L. diabolicum* sp. nov., *L. ellisiae*, *L. gaudiale*, and *L. helianthi*. Females of *L. diabolicum* and *L. ellisiae* have the postgena lineate and apical rims of T1–T2 impunctate or with minute, sparse, obscure punctures. Females of *L. gaudiale* have the tegula inner posterior margin more strongly concave and often more densely punctate laterally at midlength (IS < 1 PD); T1 anterior slope very shiny; metapostnotum rugae usually not reaching posterior margin; and postgena sometimes lineate. Females of *L. helianthi* have the mesoscutum entirely tessellate and postgena lineate.

Males of *L. eremum* sp. nov. have the tegula relatively small (reaching but not exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin weakly concave, and entirely covered in deep, crowded punctures (IS = 0 PD) except with some narrow interspaces < 1 PD laterally at midlength; metapostnotum rugose and propodeum lateral surface extensively rugulose due to very strong anastomosing rugae reaching posterior margin; face with sparse tomentum restricted to paraocular area; mesepisternum with crowded punctures (IS = 0 PD); and metasomal terga with depressed apical rims impunctate.

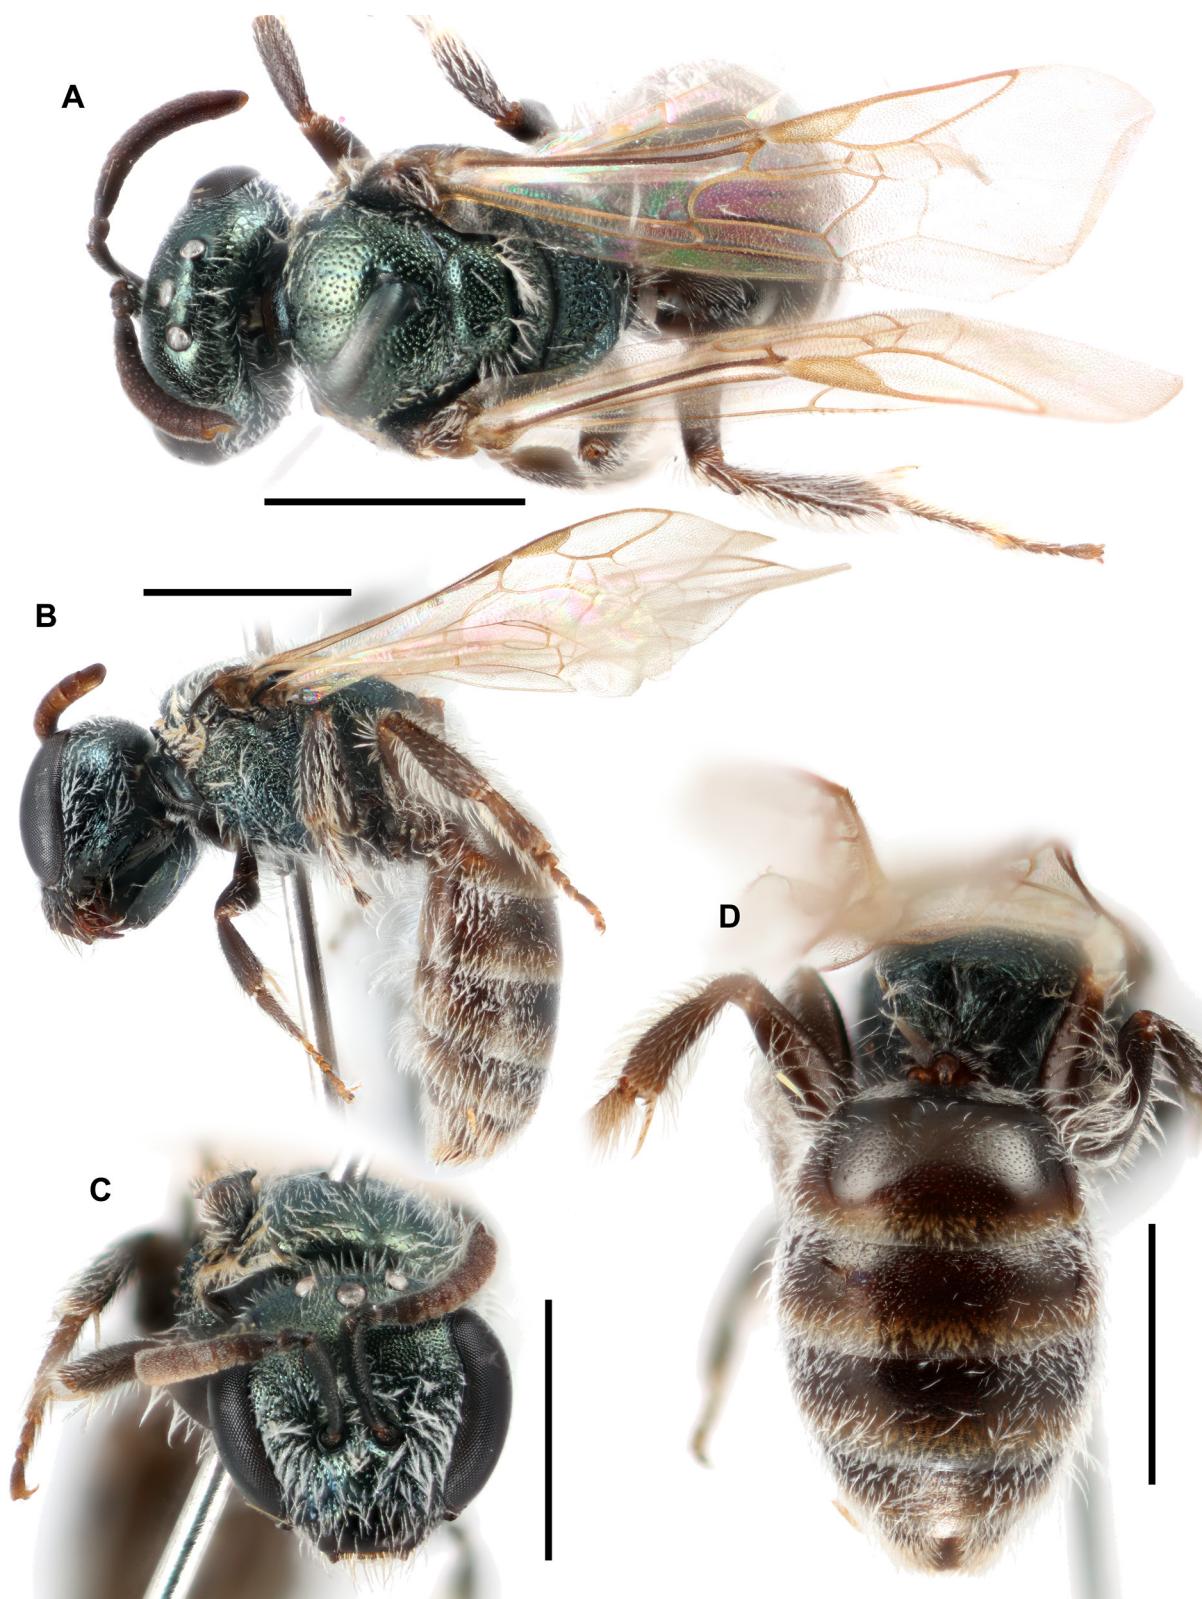

Fig. 21. *Lasioglossum (D.) eremum* sp. nov., ♀ (BBSL1070450). **A.** Dorsal habitus. **B.** Lateral habitus. **C.** Face. **D.** Metasoma and propodeum. Scale bars = 1 mm.

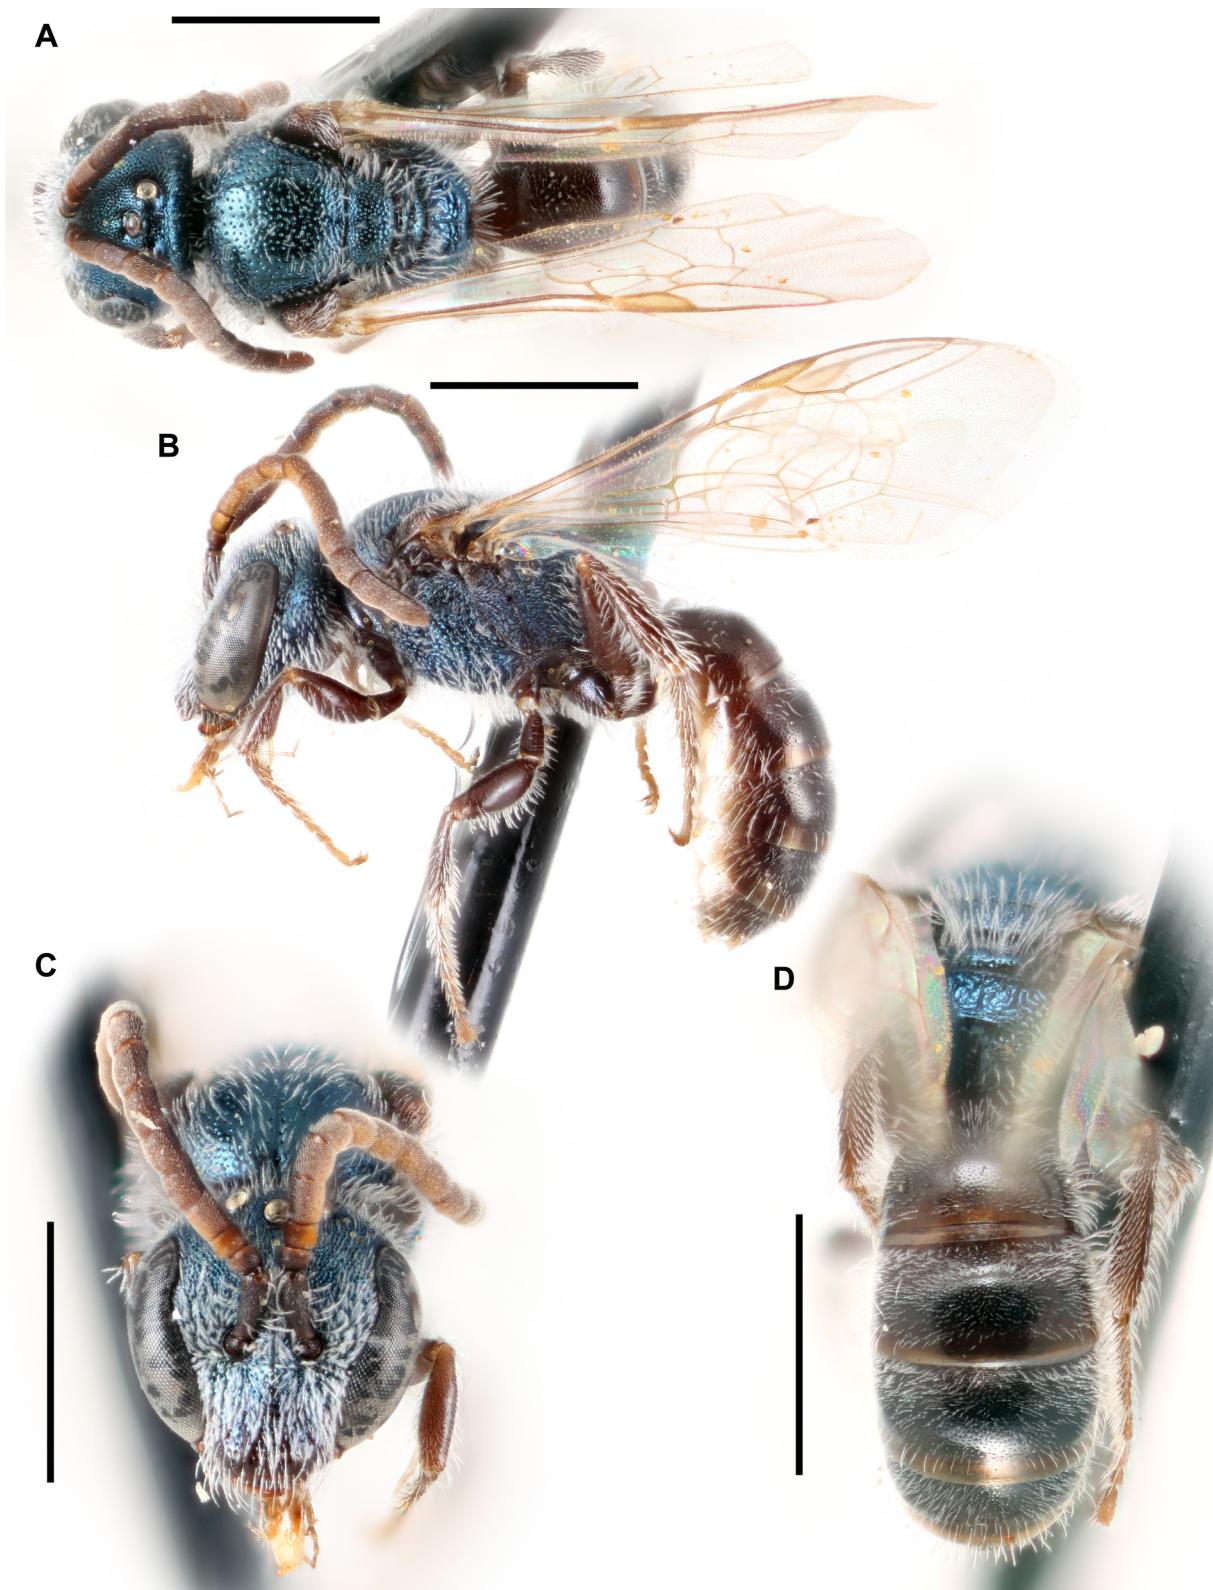

Fig. 22. *Lasioglossum (D.) eremum* sp. nov., ♂ (SEMC). **A.** Dorsal habitus. **B.** Lateral habitus. **C.** Face. **D.** Metasoma and propodeum. Scale bars = 1 mm.

Males of *L. eremum* sp. nov. are most similar to those of *L. holzenthalii* sp. nov. and members of the *L. stictaspis* species complex. Males of *L. holzenthalii* have the clypeus and supraclypeal area with sparse tomentum; tegula more sparsely punctate with more distinct interspaces (IS ≥ 0.5 PD); metapostnotum with subparallel rugae and propodeum lateral surface smooth and shiny; and metasomal terga with depressed apical rims punctate. Males in the *L. stictaspis* species complex have the face uniformly covered in dense tomentum below the eye emargination and mesepisternum usually more sparsely punctate with distinct interspaces (IS ≥ 0.5 PD).

Etymology

The specific epithet ‘*eremum*’ is the Latinized Greek adjective ‘*eremos*’ (lonely). It refers to the fact that this species is primarily known from singleton specimens in remote locations.

Description

Female

COLOURATION. Head and mesosoma blue to olive green; clypeus apex black; labrum reddish brown; mandible orange with black base and red apex; flagellum dark reddish brown dorsally, light brown ventrally. Pronotal lobe reddish brown; legs dark reddish brown; tegula black to reddish brown; wing membrane hyaline, veins with subcosta dark brown, otherwise light brown. Metasoma black with rims of terga and sterna broadly translucent brown.

PUBESCENCE. Body pile colour white. Tomentum dense on gena anteriorly, pronotal collar and lobe, space between pronotal lobe and tegula, metanotum anteriorly, T2–T3 basolaterally, and T4 throughout; sparse

on paraocular area and metepisternum. Mesoscutum pubescence thin to moderately plumose. Wing setae dark, short and dense. Acarinarial fan complete, dense. T2 fringes dense, T3 fringes dense.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense in basal fourth ($IS \leq 1$ PD), large and irregularly sparse apically ($IS < 2$ PD); supraclypeal area shiny, with punctures dense ($IS \leq 1$ PD); paraocular area shiny, with punctures dense ($IS < 1$ PD), sparser around antenna socket ($IS \leq 1$ PD); frons shiny, with punctures dense ($IS < 1$ PD); vertex shiny, with punctures dense laterally ($IS < 1$ PD), fine and sparse medially ($IS = 1–3$ PD); gena shiny, with punctures fine, moderately dense ($IS = 1–2$ PD); postgena shiny, becoming lineolate posteriorly. Tegula punctures fine, sparse ($IS = 1–3$ PD); mesoscutum shiny, becoming weakly tessellate anteromedially, with punctures moderately dense ($IS = 1–2$ PD), becoming dense on lateral and posterior margins ($IS < 1$ PD); scutellum shiny, with punctures dense ($IS < 1$ PD); metapostnotum weakly tessellate, with rugae strong, anastomosing, reaching posterior margin; preepisternum shiny with crowded punctures ($IS = 0$ PD); hypoepimeron shiny, with punctures crowded ($IS = 0$ PD); mesepisternum shiny, with punctures dense ($IS < 1$ PD); metepisternum weakly rugulose; propodeum lateral surface tessellate, posterior surface tessellate. T1 anterior slope weakly coriaceous, disc shiny, with punctures moderately dense ($IS = 1–2$ PD), becoming fine and moderately sparse on rim ($IS = 1–3$ PD) and absent in small subapicalateral boss; T2 disc shiny, with punctures moderately dense ($IS = 1–2$ PD), apical rim shiny, with punctures fine, moderately sparse ($IS = 1–3$ PD).

STRUCTURE. Face length/width ratio 0.8 (± 0.01 SD); clypeus apicolateral denticles rounded acute points; gena/eye width ratio 0.96 (± 0.06 SD). Pronotal angle obtuse; intertegular span 0.85 (± 0.07 SD) mm; mesoscutum length/width ratio 0.88 (± 0.03 SD); mesoscutum/scutellum length ratio 2.88 (± 0.17 SD); scutellum/metanotum length ratio 1.6 (± 0.2 SD); metanotum/metapostnotum length ratio 0.75 (± 0.11 SD); forewing with 3 submarginal cells; tegula enlarged, reaching posterior margin of mesoscutum; inner margin concave; tegula length 0.42 (± 0.03 SD) mm, width 0.21 (± 0.01 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina strong, straight. T2 depressed apical rim less than 50% of tergum. ($n = 9$)

VARIATION. The tegula punctures can vary from dense ($IS \leq 1$ PD) to sparse ($IS = 1–3$ PD), the inner posterior margin can be straight or weakly concave, the T1–T2 apical rim punctures can vary from moderately dense ($IS = 1–2$ PD) to sparse ($IS = 1–3$ PD), and the supraclypeal area is sometimes black or brassy.

Male

COLOURATION. Head and mesosoma blue to blue-green; clypeus apex black; labrum black; mandible orange with black base and red apex; flagellum black dorsally, light brown ventrally. Pronotal lobe dark brown; legs brown; tegula dark reddish brown; wing membrane hyaline, veins with subcosta dark brown, otherwise brown to light brown. Metasoma black with depressed apical rims of terga and sterna and downcurved lateral areas of terga translucent brown.

PUBESCENCE. Body pile colour white. Tomentum dense on pronotal collar; sparse on paraocular area and gena. Mesoscutum pubescence simple to sparsely plumose. Wing setae dark, short and sparse. Sterna pubescence moderately short (1–2 OD), sparsely plumose, sparse.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense ($IS < 1$ PD); supraclypeal area shiny, with punctures dense ($IS < 1$ PD); paraocular area shiny, with punctures dense ($IS < 1$ PD); frons shiny, with punctures crowded ($IS = 0$ PD); vertex shiny, with punctures dense laterally ($IS < 1$ PD), moderately dense medially ($IS = 1–2$ PD); gena shiny, with punctures fine, moderately sparse ($IS = 1–2$ PD); postgena lineate. Tegula punctures crowded ($IS = 0$ PD); mesoscutum shiny, becoming weakly tessellate anteromedially, with punctures dense ($IS \leq 1$ PD), becoming sparse anteromedially ($IS = 1–3$ PD); scutellum shiny, with punctures dense ($IS < 1$ PD), becoming sparser medially ($IS = 1–2$ PD); metanotum shiny and finely,

densely punctate (IS < 1 PD); metapostnotum shiny, with rugae strong, anastomosing, reaching posterior margin; preepisternum areolate; hypoepimeron shiny, with punctures crowded (IS = 0 PD); mesepisternum shiny, with punctures crowded (IS = 0 PD); metepisternum rugulose; propodeum lateral surface rugulose, becoming smooth and imbricate medially, with punctures crowded (IS = 0 PD), becoming slightly sparser medially (IS < 1 PD), posterior surface shiny with crowded punctures (IS = 0 PD). T1 anterior slope shiny, disc shiny, with punctures sparse (IS = 1–3 PD), becoming very sparse in large subapicolateral boss (IS > 3 PD) and absent on rim; T2 disc shiny, with punctures dense (IS ≤ 1 PD), becoming moderately sparse near premarginal line (IS = 1–3 PD), apical rim shiny, with punctures absent.

STRUCTURE. Face length/width ratio 0.84 (± 0.02 SD); gena/eye width ratio 0.8 (± 0.05 SD). Pronotal angle obtuse; intertegular span 0.74 (± 0.01 SD) mm; mesoscutum length/width ratio 0.95 (± 0.06 SD); mesoscutum/scutellum length ratio 2.61 (± 0.27 SD); scutellum/metanotum length ratio 1.74 (± 0.02 SD); metanotum/metapostnotum length ratio 0.82 (± 0.14 SD); forewing with 3 submarginal cells; tegula enlarged, reaching posterior margin of mesoscutum; inner posterior margin weakly concave; tegula length 0.43 (± 0.01 SD) mm, width 0.22 (± 0.01 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina absent. (n = 2)

GENITALIA. Not examined.

VARIATION. The one other male specimen examined has the mandible completely dark, scutellum entirely densely punctate (IS < 1 PD), and both forewings with only two submarginal cells.

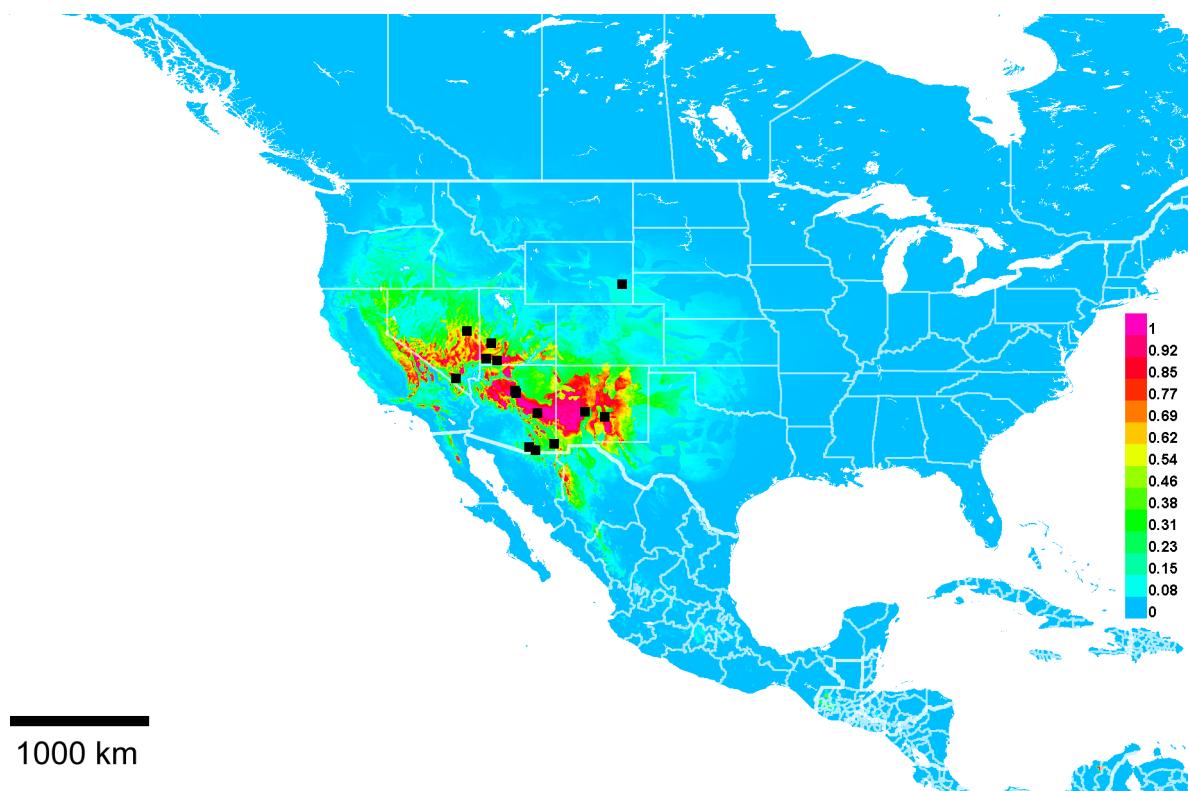

Fig. 23. Georeferenced collection records of *Lasioglossum (D.) eremum* sp. nov. (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

Range

Mountains from Nevada to New Mexico and north to Wyoming (Fig. 23).

Floral hosts

APOCYNACEAE: *Apocynum* L.: *A. androsaemifolium* L. • ASTERACEAE: *Chrysanthemus* • *Heterotheca*: *H. subaxillaris* • EUPHORBIACEAE: *Euphorbia*: *E. albomarginata* Torr. & A. Gray • FABACEAE: *Melilotus*: *M. officinalis* • PAPAVERACEAE: *Argemone*.

DNA barcodes

Two confirmed sequences available (BOLD process IDs: DLII1060-07, DLIII183-19). There is a small amount of divergence within these sequences (0.16% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. elisiae* (2.68% minimum interspecific p-distance). Six fixed nucleotide substitutions distinguish *L. erenum* sp. nov. from all other Nearctic species of the *L. gemmatum* complex: 15(C), 63(C), 75(G), 162(C), 199(A), and 573(A) ([Supp. file 2](#)).

Comments

Rare. *Lasioglossum erenum* sp. nov. is evidently restricted to rugged, relatively high elevation terrain. It is not found in flat plains or deserts except for a single specimen from Carrizozo, New Mexico, collected by Raymond Beamer among a very long series of *L. coactus*. It is possible that this specimen is mislabeled and actually belongs to the long series of *L. erenum* from Carrizo Creek, Arizona, which were collected one week later by Lucy Beamer. Alternatively, the mountains or extremely rugged lava fields near Carrizozo may be suitable habitat for this species.

Lasioglossum (Dialictus) gaudiale (Sandhouse, 1924)

Figs 24–26, 76E, 91B, 94A, 103A, 104A, 114A

Halictus (Chloralictus) gaudialis Sandhouse, 1924: 23 (holotype, ♂, deposited in USNM, type no. 26418, examined).

Halictus (Chloralictus) gaudialis – Michener 1936: 283 (relationship to *helianthi*).

Lasioglossum (Chloralictus) tegulariforme – Michener 1951: 1118 (in part, synonymy, catalogue).

Dialictus tegulariformis – Hurd 1979: 1972 (in part, catalogue). — Moure & Hurd 1987: 134 (in part, catalogue).

Lasioglossum (Dialictus) gaudiale – Gardner & Gibbs 2022: 28 (resurrection from synonymy).

Diagnosis

Females of *L. gaudiale* have the tegula relatively small (reaching and sometimes slightly exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin strongly concave and a small rounded posterior projection, and usually densely punctate (IS \leq 1 PD, rarely up to 2 PD); T1 anterior slope polished and mirror-smooth (rarely with very weak microsculpture basally); gena about as wide as eye in lateral view; metapostnotum usually shiny basally with strong subparallel rugae not reaching the posterior margin (sometimes dull, with rugae anastomosing, or rugae reaching posterior margin, but never all at once); mesoscutum with no tomentum; T3 without a subapical band of tomentum; and metasoma usually black to brown (rarely red-orange). In many cases, the scutellum is significantly more coarsely and sparsely punctate than the mesoscutum (IS = 1–2 PD), but this is unreliable as a primary diagnostic character.

Females of *L. gaudiale* are most similar to those of *L. angelicum* sp. nov., *L. erenum* sp. nov., *L. gloriosum* sp. nov., *L. indagator* sp. nov., and *L. pseudotegulare*, all of which (except *L. indagator*) have the gena

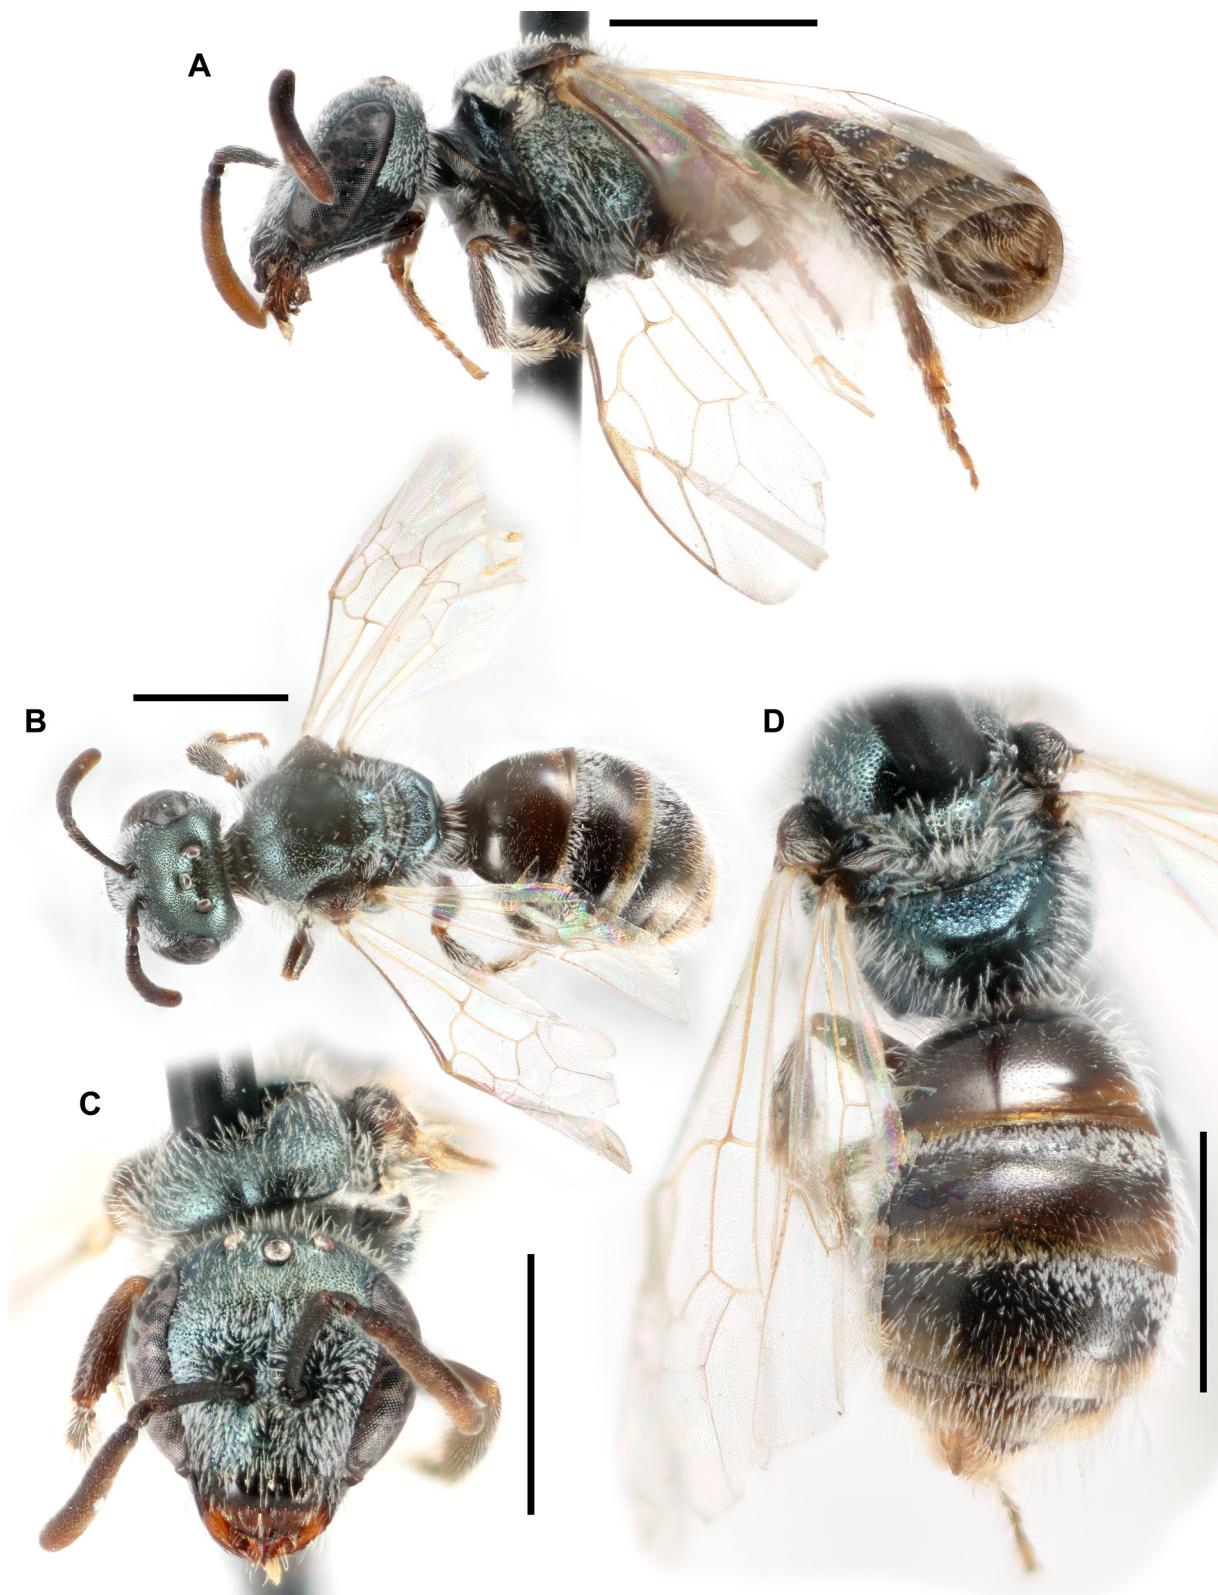

Fig. 24. *Lasioglossum (D.) gaudiale* (Sandhouse, 1924), ♀ (UCMC 0260263). **A.** Lateral habitus. **B.** Dorsal habitus. **C.** Face. **D.** Metasoma and propodeum. Scale bars = 1 mm.

narrower than eye in lateral view and scutellum usually finely and densely punctate ($IS < 1 PD$). In addition, females of *L. eremum* sp. nov. have the metapostnotum with anastomosing rugae reaching the posterior margin and T1 anterior slope coriarious. Females of *L. gloriosum* have the T1 anterior slope coriarious, mesoscutum lateral and posterior margins with dense tomentum, metapostnotum rugae usually reaching the posterior margin, and metasoma red-orange. Females of *L. indagator* have the tegula sparsely punctate ($IS = 1–3 PD$) and inner posterior margin weakly concave. Females of *L. pseudotegulare* have

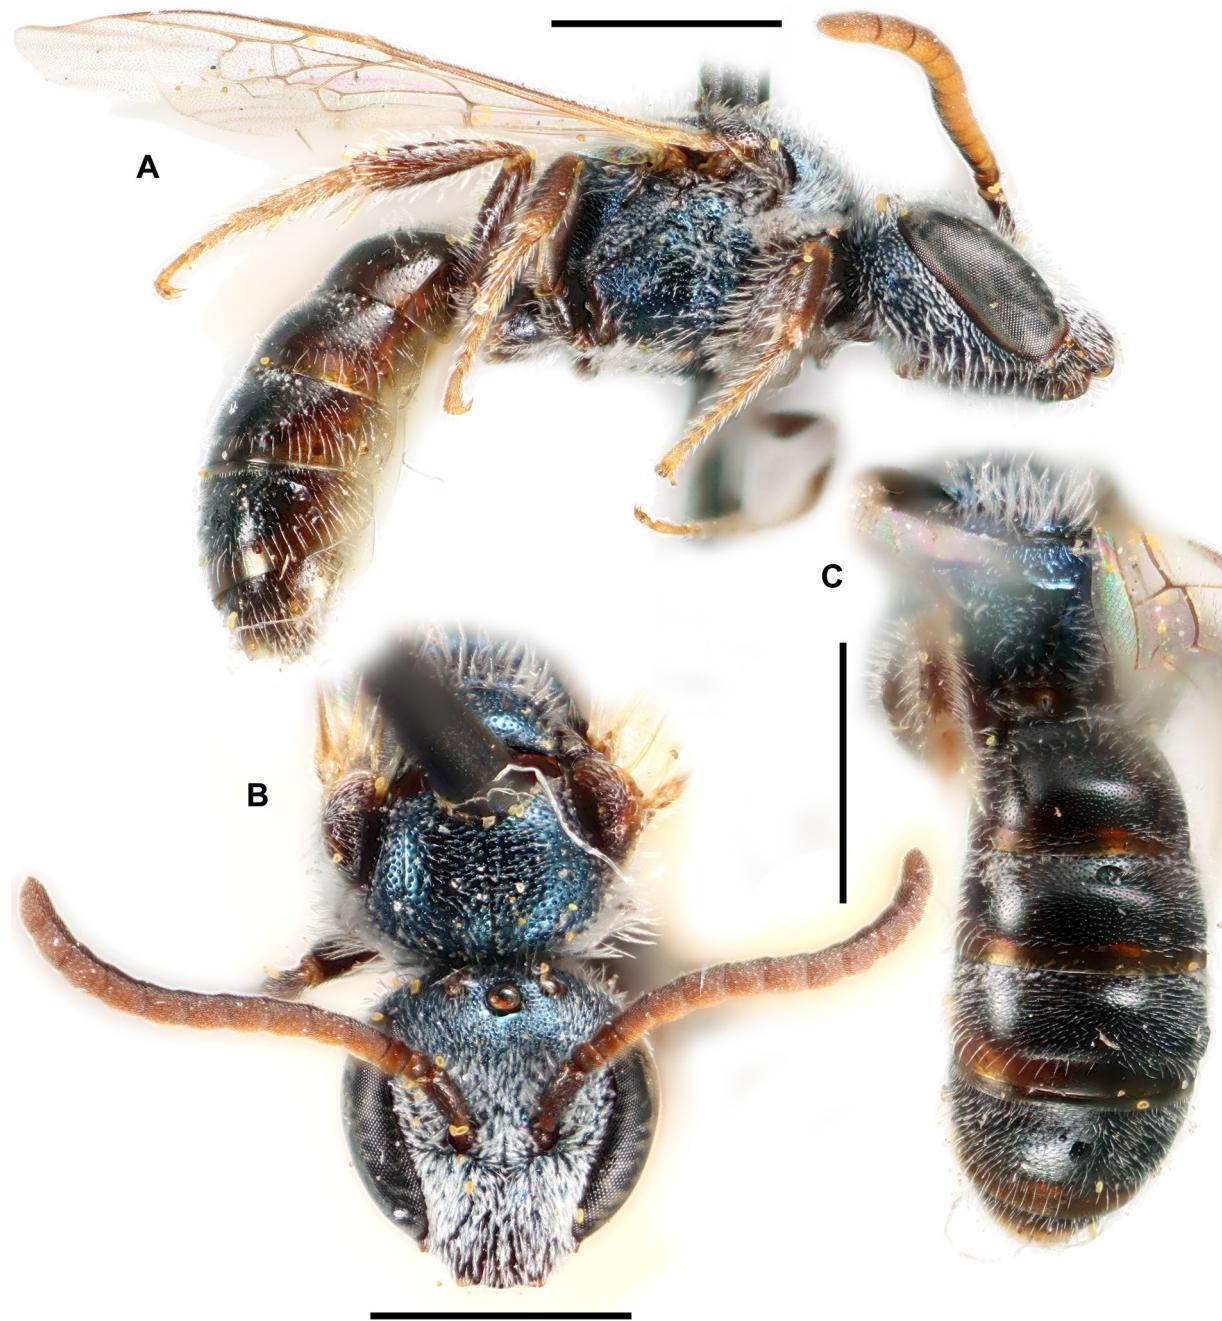

Fig. 25. *Lasioglossum (D.) gaudiale* (Sandhouse, 1924), ♂, holotype (USNM 26418). A. Lateral habitus. B. Face and mesonotum. C. Metasoma and propodeum. Scale bars = 1 mm.

the metapostnotum entirely dull with fine rugae and tegula very large (exceeding posterior margin of mesoscutum in dorsal view) and more densely punctate (IS < 1 PD). Females of *L. angelicum* sp. nov. have a similarly large tegula.

Males of *L. gaudiale* have the tegula relatively small (reaching or slightly exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin strongly concave and a narrow posterior point, and usually densely punctate (IS < 1 PD); face relatively narrow (length/width ratio usually > 0.83) with dense tomentum below the upper ocular tangent (often surrounding the median ocellus); metapostnotum usually shiny with strong subparallel rugae not reaching posterior margin; mesoscutum usually densely punctate (IS ≤ 1 PD) and fringed with tomentum; mesepisternum somewhat coarsely punctate with distinct interspaces (IS ≤ 1 PD); preepisternum and metepisternum with sparse appressed tomentum; T2–T3 with abundant basolateral tomentum; and head and mesosoma integument usually deep blue.

Males of *L. gaudiale* are most similar to those of *L. gloriosum* sp. nov. and *L. indagator* sp. nov. Both of these species have the face broad (length/width ratio ≤ 0.83) and preepisternum and metepisternum with more abundant tomentum. In addition, males of *L. gloriosum* have the mesepisternum very densely punctate (IS < 1 PD); metapostnotum usually with anastomosing rugae reaching posterior margin; and integument usually greener. Males of *L. indagator* have the metapostnotum with very short parallel rugae not reaching the posterior margin; tegula inner posterior margin more weakly concave, forming a blunt angle posteriorly, and usually moderately sparsely punctate laterally (IS = 1–2 PD); and mesoscutum usually slightly more sparsely punctate (IS = 1–2 PD).

Etymology

Sandhouse (1924) formed the specific epithet ‘gaudialis’ from the Latin noun ‘gaudium’ (joy) and the adjectival suffix ‘-alis’ (state or condition of), together meaning ‘joyful’.

Range

California and Mojave, Sonoran, and Chihuahuan Deserts, with some outliers in eastern Colorado, eastern Texas, and Aguascalientes (Fig. 26).

Floral hosts

ASTERACEAE: *Baileya*: *B. multiradiata* • *Chrysothamnus* • *Gutierrezia*: *G. microcephala* • *Haplopappus* Cass. • *Solidago* L. • *Stephanomeria*: *S. pauciflora* (Torr.) A.Nelson • BIGNONIACEAE: *Tecoma* Juss.: *T. stans* (L.) Juss. ex Kunth • BORAGINACEAE: *Cryptantha* Lehm. ex G.Don • *Heliotropium* L.: *H. curassavicum* L. • *Nama* • PHACELIA: *P. ciliata* Benth. • *P. fremontii* Torr. • BRASSICACEAE: *Lepidium* • CLEOMACEAE: *Cleomella* DC.: *C. obtusifolia* Torr. & Frém. • *Oxystylis* Torr. & Frém.: *O. lutea* Torr. &

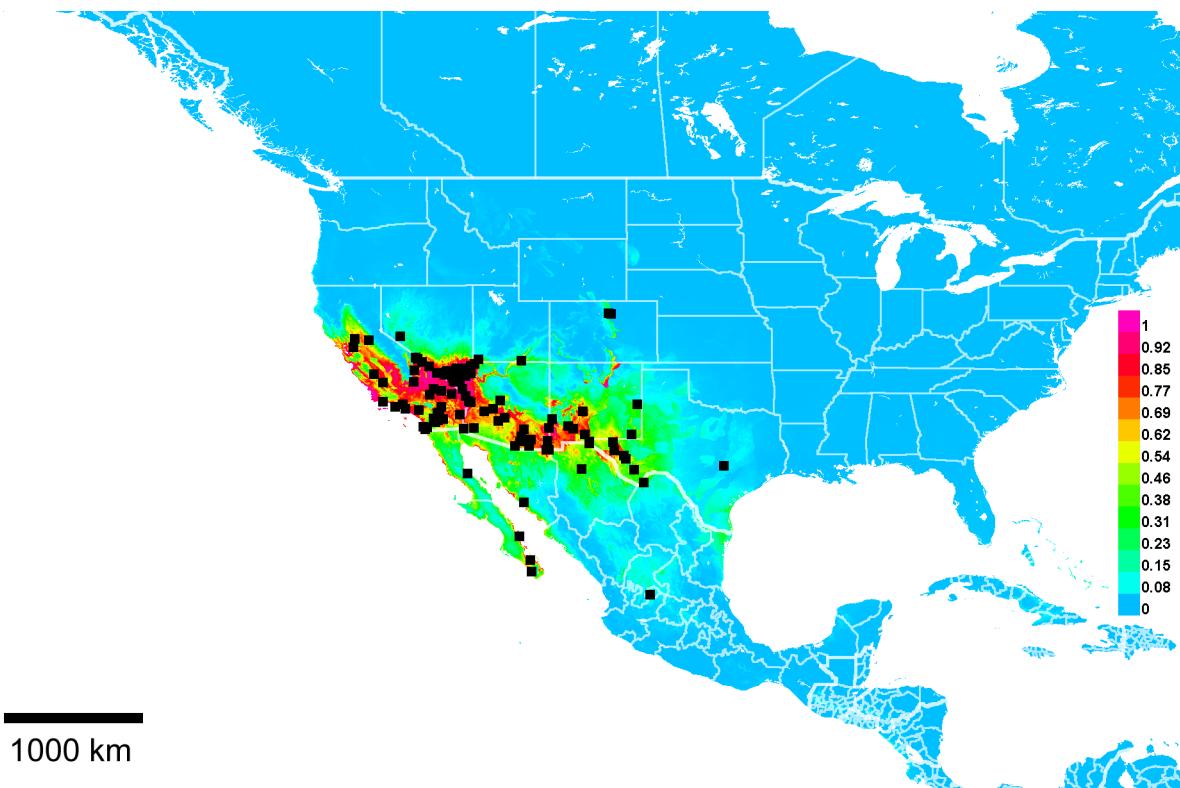

Fig. 26. Georeferenced collection records of *Lasioglossum (D.) gaudiale* (Sandhouse, 1924) (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

Frém. • CONVOLVULACEAE Juss.: *Cressa* L.: *C. truxillensis* Kunth • EUPHORBIACEAE: *Croton*: *C. wigginsii* • *Euphorbia*: *E. albomarginata* • FABACEAE: *Astragalus* L. • *Cercidium* • *Medicago*: *M. sativa* • *Melilotus*: *M. officinalis*: *M. o.* subsp. *alba* • LOASACEAE: *Eucnide* Zucc.: *E. urens* Parry • *Mentzelia* • MALVACEAE: *Gossypium* • PAPAVERACEAE: *Arctomecon*: *A. californicum* • *Argemone*: *A. pleiacantha* Greene: *A. p.* subsp. *pinnatisecta* G.B.Ownbey • PLANTAGINACEAE: *Penstemon*: *P. fruticiformis* Coville • POLYGONACEAE: *Eriogonum*: *E. inflatum* Torr. & Frém. • *E. rixfordii* S.Stokes • SOLANACEAE: *Solanum*: *S. elaeagnifolium* • TAMARICACEAE: *Tamarix*: *T. aralensis* Bunge • *T. ramosissima*.

DNA barcodes

Twelve confirmed sequences available, two haplotypes (BOLD process IDs: BEECB223-07, BEECB225-07, BEECB226-07, DLII648-07, NCBEE405-21, NCBEE406-21, NCBEE617-21 (haplotype 1); DLIII156-19, DLIII226-20, DLIII228-20, DLIII229-20, DLIII230-20 (haplotype 2)). There is a large amount of divergence within these sequences (2.61% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. helianthi* (1.07% minimum interspecific p-distance). No fixed nucleotide substitutions distinguish all *L. gaudiale* from all other Nearctic species of the *L. gemmatum* complex, but two fixed substitutions distinguish haplotype 1, and two fixed substitutions distinguish haplotype 2: 205(C) and 357(C) (haplotype 1); 408(A) and 411(T) (haplotype 2) ([Supp. file 2](#)).

Comments

Common in Nevada and California, becoming rare further east. *Lasioglossum gaudiale* is especially abundant in the Mojave Desert.

Lasioglossum (Dialictus) gloriosum sp. nov.

[urn:lsid:zoobank.org:act:863681D4-D141-45E1-A3F0-E49F2334394B](#)

Figs 27–29, 76F, 83A, 84A, 102D, 103B, 104B, 105A

Diagnosis

Females of *L. gloriosum* sp. nov. have the tegula relatively large (maximum length more than half ITS and exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin weakly concave, and densely punctate (IS \leq 1 PD); mesoscutum, scutellum, and mesepisternum shiny and very densely punctate (IS $<$ 1 PD) (mesoscutum becoming tessellate and slightly more sparsely punctate anteromedially); metapostnotum shiny with coarse rugae reaching posterior margin; mesoscutum lateral and posterior margins, metanotum, and pleura with abundant tomentum; T1 anterior slope coriarious; and metasoma red-orange.

Females of *L. gloriosum* sp. nov. are most similar to those of *L. diabolicum* sp. nov., *L. gaudiale*, and *L. indagator* sp. nov. Females of *L. diabolicum* and *L. gaudiale* have the mesoscutum more sparsely punctate between parapsidal lines (some IS $>$ 1 PD) and the mesoscutum, metanotum, and pleura with tomentum sparse or absent. In addition, females of *L. diabolicum* and *L. indagator* have the tegula smaller (not exceeding posterior margin of mesoscutum in dorsal view) and usually more sparsely punctate laterally at midlength (IS \geq 1 PD). Females of *L. indagator* also have the metapostnotum rugae not reaching posterior margin. Females of *L. gaudiale* have the gena about as wide as eye in lateral view, metapostnotum rugae usually not reaching posterior margin, T1 anterior slope shiny, and scutellum often sparsely punctate (IS = 1–2 PD). Some other species in the *L. stictaspis* species complex can be very similar, but can be separated by the same characters as for *L. diabolicum* except for the tegula.

Males of *L. gloriosum* sp. nov. have the tegula very large (maximum length \geq 60% ITS and exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin somewhat strongly concave

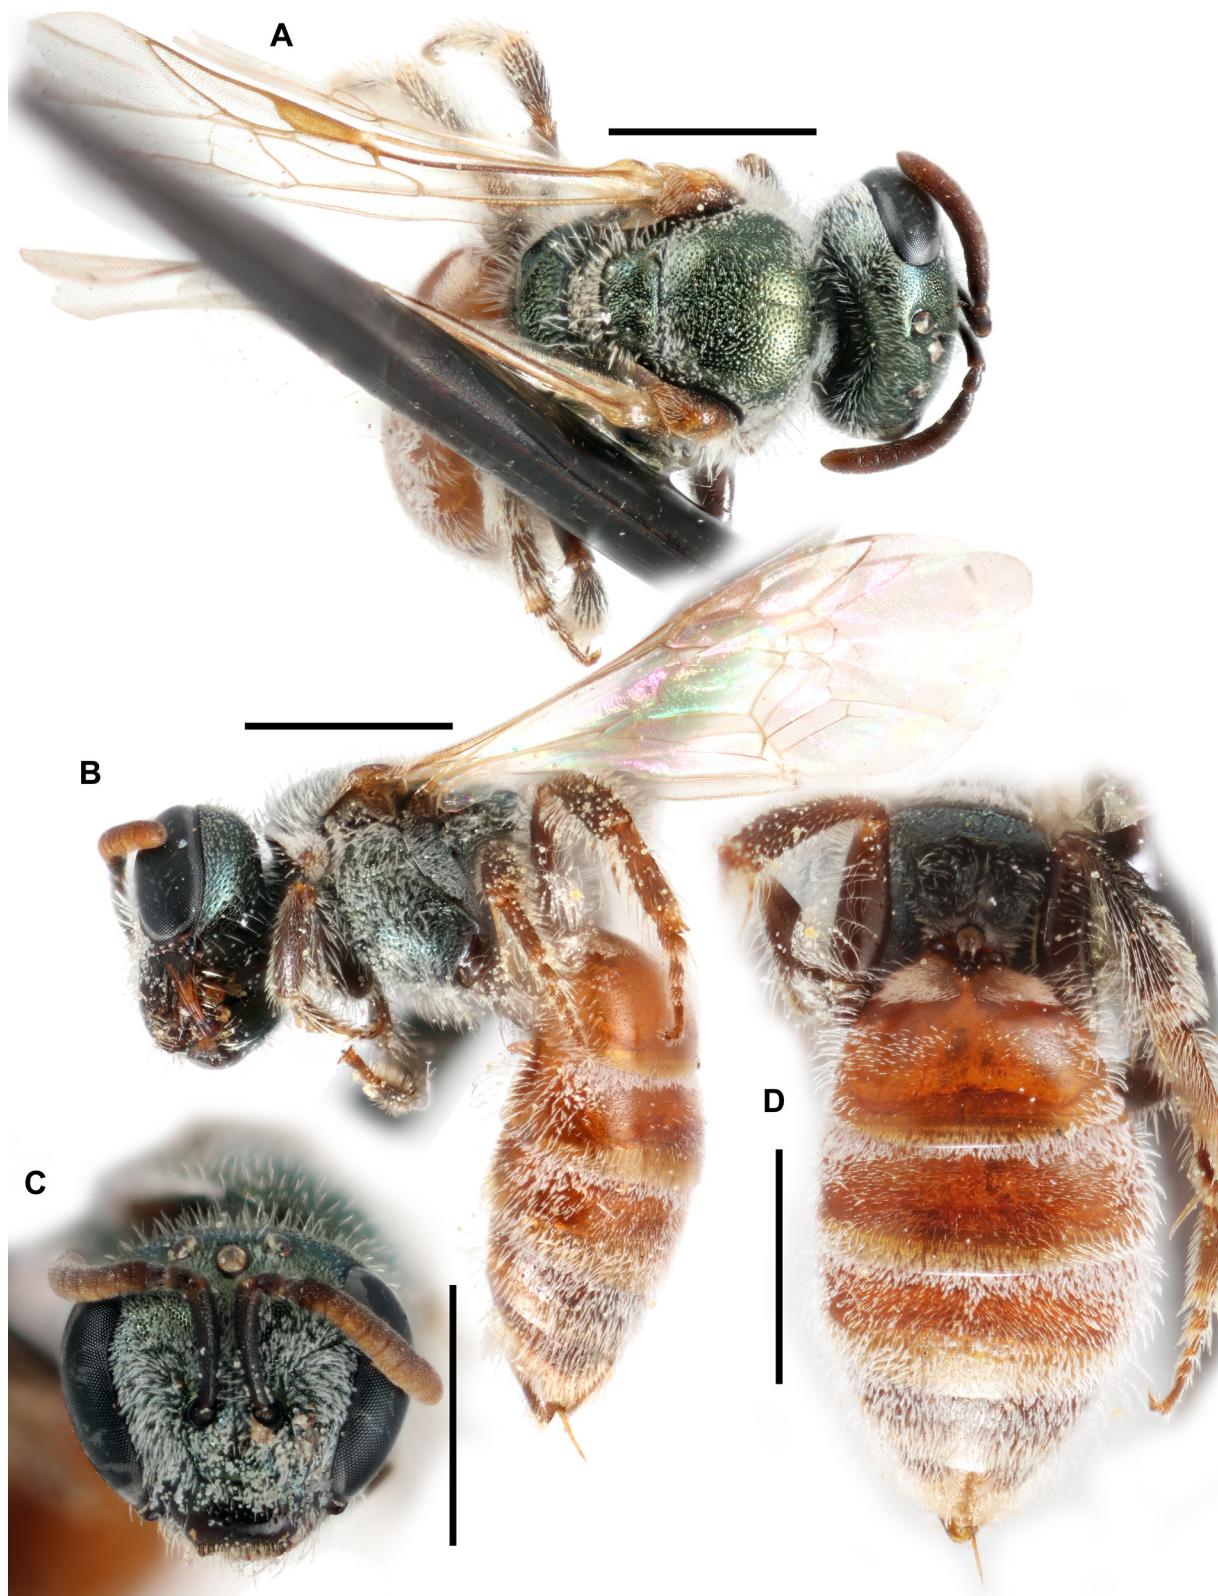

Fig. 27. *Lasioglossum (D.) gloriosum* sp. nov., ♀, holotype (CUIC). **A.** Dorsal habitus. **B.** Lateral habitus. **C.** Face. **D.** Metasoma and propodeum. Scale bars = 1 mm.

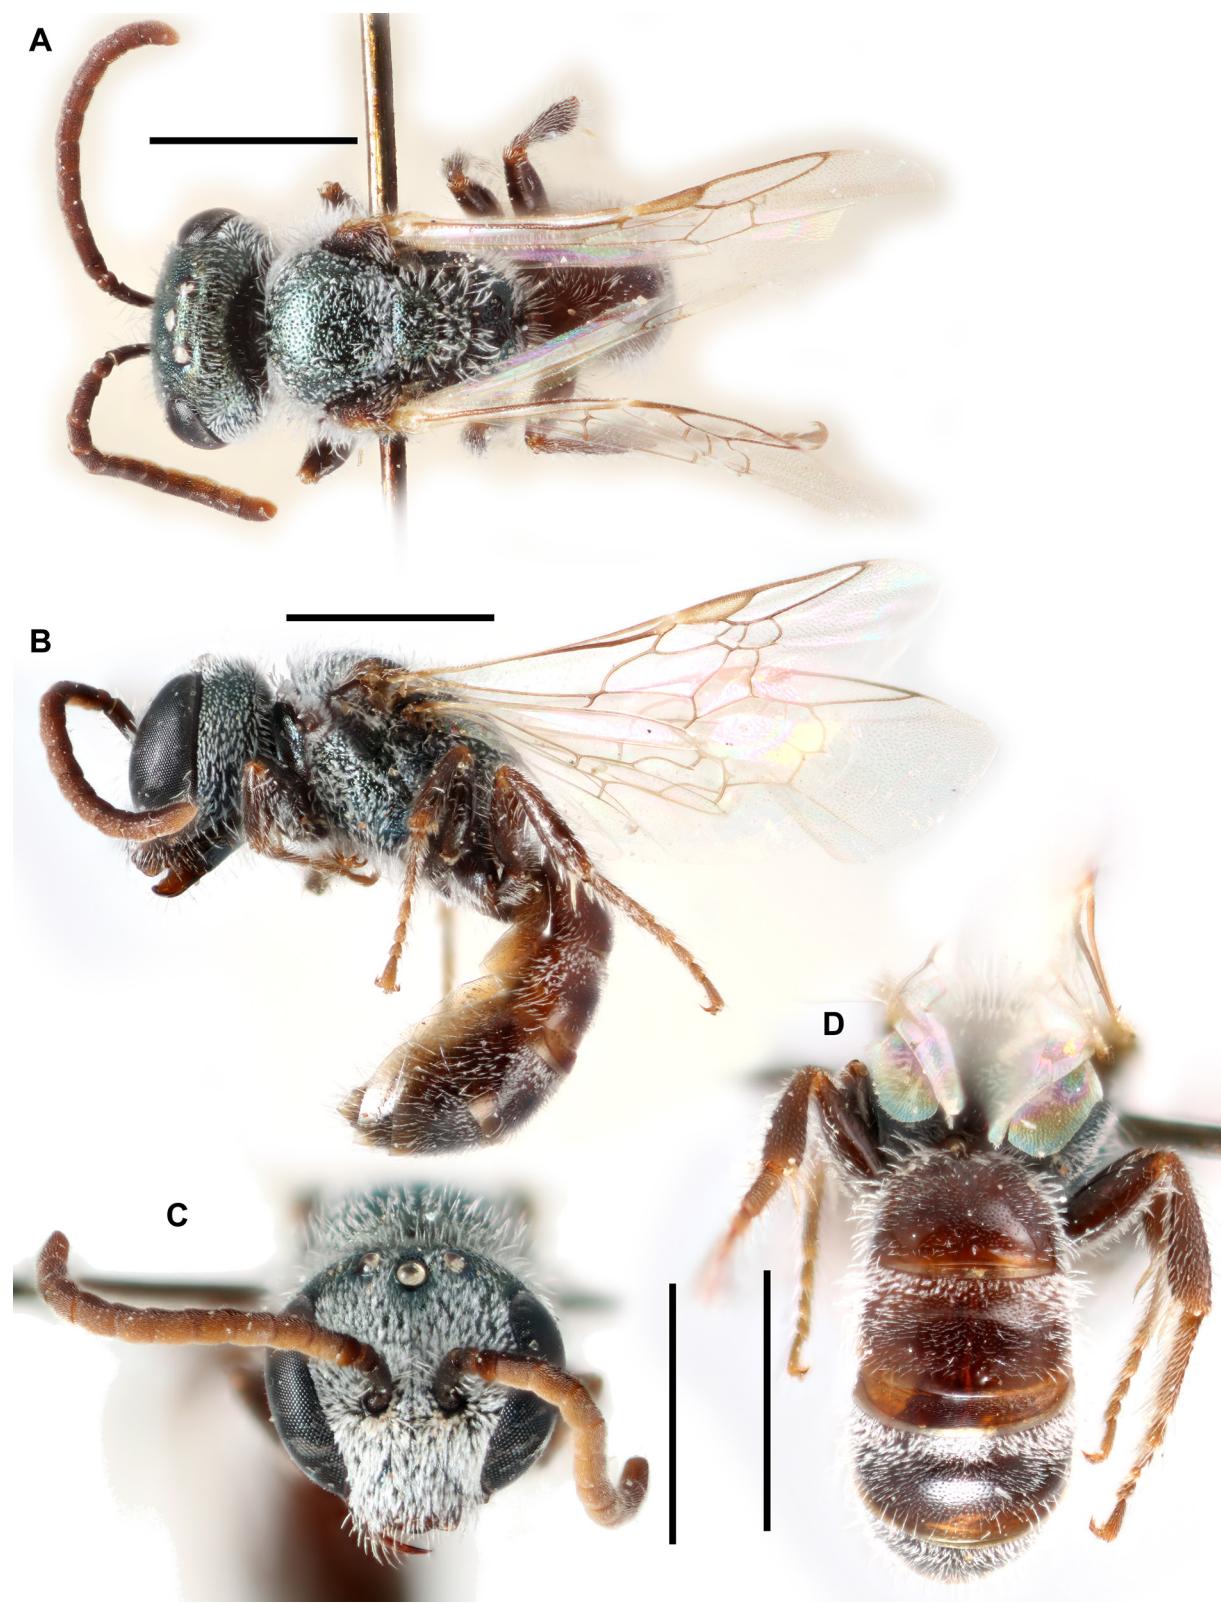

Fig. 28. *Lasioglossum (D.) gloriosum* sp. nov., ♂, from Utah, Bluff (CUIC). **A.** Dorsal habitus. **B.** Lateral habitus. **C.** Face. **D.** Metasoma. Scale bars = 1 mm.

with a rounded posterior projection, and densely punctate (IS < 1 PD); face broad (length/width ratio ≤ 0.83) and covered with very dense tomentum up to the median ocellus; mesoscutum usually densely punctate (IS ≤ 1 PD) and fringed with tomentum; pleura with extensive tomentum; metapostnotum shiny with strong subparallel rugae usually reaching posterior margin; T2–T3 with extensive basolateral tomentum; and head and mesosoma usually blue-green to olive green. They are most similar to those of *L. gaudiale* and *L. indagator* sp. nov. See the diagnosis for *L. gaudiale* for a comparative diagnosis between these three species.

Etymology

The specific epithet ‘*gloriosum*’ is an adjective derived from the Latin noun ‘*gloria*’ (glory, fame) plus the adjectival suffix ‘-osum’ (fullness or abundance). It refers to the numerous distinctive characters possessed by this species which make it highly recognisable. An appropriate translation would be the glorious sweat bee.

Description

Female

COLOURATION. Head and mesosoma blue-green to olive green; clypeus apex black; labrum reddish brown; mandible orange with black base and red apex; flagellum reddish brown dorsally, orange ventrally. Pronotal lobe brown; legs reddish brown; tegula brown to orange; wing membrane hyaline, veins with

subcosta dark brown, otherwise brown to pale amber. Metasoma orange with dark spiracular spots on T3–T4 and rims of terga and sterna broadly translucent yellow.

PUBESCENCE. Body pile colour white. Tomentum dense on paraocular area, gena, pronotal collar and lobe, space between pronotal lobe and tegula, margins of mesoscutum, metanotum medially, metepisternum, T2–T3 basally, and T4 throughout; sparse on supraclypeal area, upper half of clypeus, preepisternum, hypoepimeron, and mesepisternum. Mesoscutum pubescence thin to densely plumose. Wing setae light and dark, short and dense. Acinarial fan complete, dense. T2 fringes dense, T3 fringes dense.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense in basal half ($IS < 1$ PD), nearly impunctate apically; supraclypeal area shiny, with punctures dense ($IS \leq 1$ PD); paraocular area shiny, with punctures crowded ($IS = 0$ PD); frons shiny, with punctures crowded ($IS = 0$ PD); vertex shiny, with punctures crowded laterally ($IS = 0$ PD), becoming sparse ($IS = 1–3$ PD) and diversopunctate medially; gena shiny, with punctures dense ($IS < 1$ PD); postgena lineolate. Tegula punctures crowded ($IS = 0$ PD), becoming slightly sparser medially ($IS \leq 1$ PD); mesoscutum shiny, becoming tessellate anteromedially, with punctures dense ($IS \leq 1$ PD); scutellum shiny, with punctures dense ($IS \leq 1$ PD); metapostnotum weakly tessellate, with rugae strong, subparallel, reaching posterior margin; preepisternum areolate; hypoepimeron shiny, with punctures crowded ($IS = 0$ PD); mesepisternum shiny, with punctures dense ($IS < 1$ PD); metepisternum ruguloso-lineate dorsally, becoming tessellate ventrally; propodeum lateral surface tessellate, posterior surface weakly tessellate. T1 anterior slope coriarious, disc weakly coriarious, with punctures fine, moderately dense ($IS = 1–2$ PD), becoming minute and sparse on rim laterally ($IS = 1–3$ PD) and absent in small subapicalateral boss and on rim medially; T2 disc shiny, with punctures fine, moderately dense ($IS = 1–2$ PD), apical rim weakly coriarious, with punctures minute, sparse ($IS = 1–4$ PD).

STRUCTURE. Face length/width ratio 0.77 (± 0.01 SD); clypeus apicolateral denticles rounded obtuse points; gena/eye width ratio 0.84 (± 0.08 SD). Pronotal angle obtuse; intertegular span 0.79 (± 0.05 SD) mm; mesoscutum length/width ratio 0.94 (± 0.03 SD); mesoscutum/scutellum length ratio 2.89 (± 0.19 SD); scutellum/metanotum length ratio 1.52 (± 0.09 SD); metanotum/metapostnotum length ratio 0.85 (± 0.11 SD); forewing with 3 submarginal cells; tegula enlarged, exceeding posterior margin of mesoscutum; inner margin concave; tegula length 0.45 (± 0.02 SD) mm, width 0.24 (± 0.01 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina weak, straight. T2 depressed apical rim less than 50% of tergum. ($n = 10$)

VARIATION. The pronotal lobe can vary from brown to orange, the clypeus apical half can vary from densely punctate ($IS \leq 1$ PD) to nearly impunctate, the T1–T2 disc punctures can vary from moderately dense ($IS = 1–2$ PD) to sparse ($IS = 1–3$ PD), and the T1–T2 apical rims can be punctate or impunctate.

Male

COLOURATION. Head and mesosoma blue-green to olive green; clypeus apex black; labrum reddish brown; mandible orange with black base and red apex; flagellum reddish brown dorsally, orange ventrally. Pronotal lobe black; legs reddish brown; tegula reddish brown; wing membrane hyaline, veins with subcosta dark brown, otherwise brown to light brown. Metasoma black with depressed apical rims of terga and sterna and downcurved lateral areas of terga translucent reddish brown.

PUBESCENCE. Body pile colour white. Tomentum dense on face below lateral ocelli, pronotal collar and lobe, space between pronotal lobe and tegula, metepisternum, and T2–T3 basally; sparse on gena, scutum lateral and posterior margins, preepisternum, mesepisternum, and T4 basally. Mesoscutum pubescence mostly densely plumose with sparse simple setae medially. Wing setae dark, short and sparse. Sterna pubescence short (0.5–1.5 OD), moderately plumose, sparse.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense ($IS < 1$ PD); supraclypeal area shiny, with punctures dense ($IS \leq 1$ PD); paraocular area shiny, with punctures dense ($IS < 1$ PD); frons shiny, with punctures crowded ($IS = 0$ PD); vertex shiny, with punctures dense ($IS < 1$ PD); gena shiny, with punctures dense ($IS < 1$ PD); postgena lineate. Tegula punctures crowded ($IS = 0$ PD) and indistinct, becoming rugulose on inner margin and slightly sparser ($IS \leq 1$ PD) and more distinct on outer margin; mesoscutum shiny, with punctures dense ($IS < 1$ PD); scutellum shiny, with punctures dense ($IS < 1$ PD); metanotum rugulose; metapostnotum shiny to tessellate, with rugae strong, anastomosing, reaching posterior margin; preepisternum areolate; hypoepimeron shiny, with punctures crowded ($IS = 0$ PD); mesepisternum shiny, with punctures dense ($IS < 1$ PD); metepisternum finely areolate, becoming smooth dorsally; propodeum lateral surface shiny, with punctures dense ($IS < 1$ PD), becoming crowded dorsally ($IS = 0$ PD), posterior surface shiny and moderately densely punctate ($IS = 1-2$ PD). T1 anterior slope shiny, disc shiny, with punctures dense ($IS \leq 1.5$ PD), absent in small subapicalateral boss and on rim medially; T2 disc shiny, with punctures dense ($IS \leq 1.5$ PD), apical rim shiny, with punctures absent.

STRUCTURE. Face length/width ratio 0.8 (± 0.02 SD); gena/eye width ratio 0.71 (± 0.04 SD). Pronotal angle obtuse; intertegular span 0.7 (± 0.04 SD) mm; mesoscutum length/width ratio 0.92 (± 0.03 SD); mesoscutum/scutellum length ratio 2.67 (± 0.09 SD); scutellum/metanotum length ratio 1.78 (± 0.18 SD); metanotum/metapostnotum length ratio 0.73 (± 0.08 SD); forewing with 3 submarginal cells; tegula enlarged, exceeding posterior margin of mesoscutum in dorsal view; inner posterior margin strongly concave, with broadly rounded projection angled toward axilla posteriorly; tegula length 0.43 (± 0.03 SD) mm, width 0.2 (± 0.02 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina absent. (n = 5)

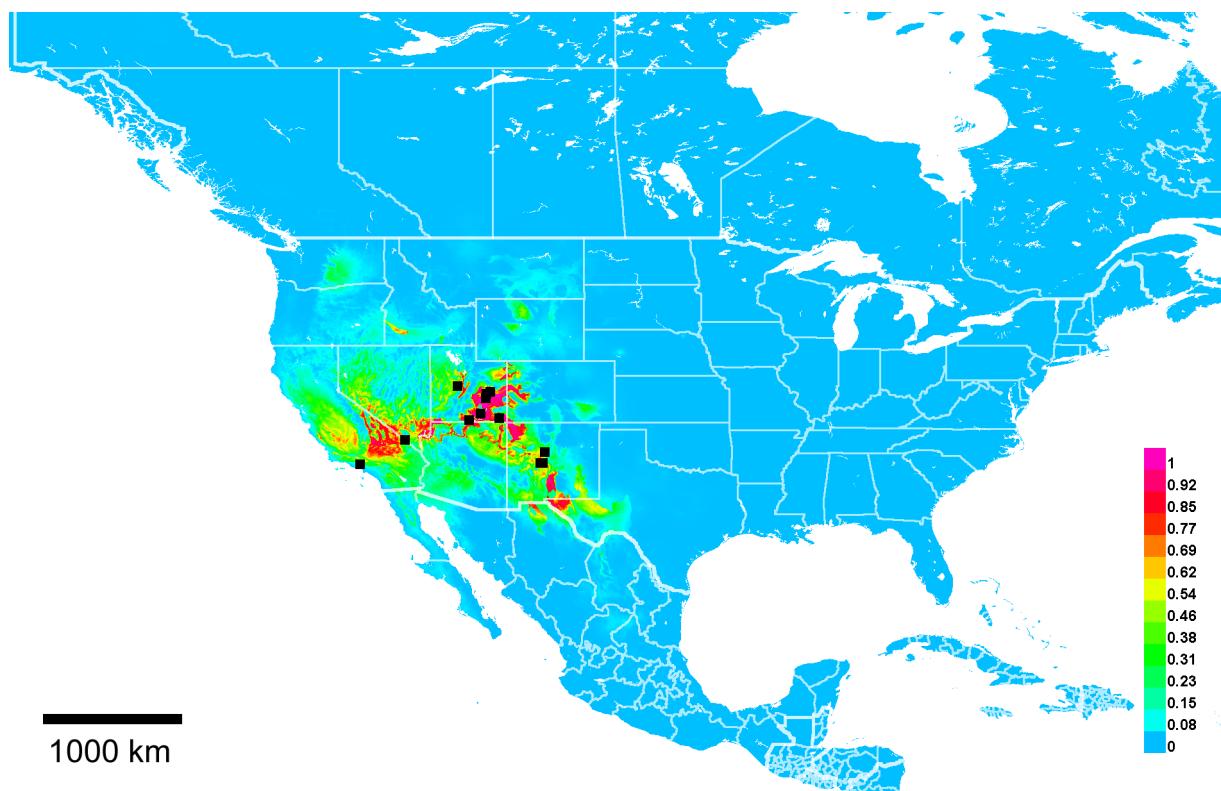

Fig. 29. Georeferenced collection records of *Lasioglossum (D.) gloriosum* sp. nov. (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

GENITALIA. As in Fig. 76F. Gonocoxite about 1.5 times as broad as gonostylus. Gonostylus boot-shaped, strongly concave on outer margin and sharply angled at inner basal margin, with sparse long setae dorsally and short setae along inner margin. Penis valves parallel, with sparse short setae laterally. Retorse lobe not examined.

VARIATION. The mesoscutum and metasoma punctures can vary from dense ($IS < 1$ PD) to moderately dense ($IS = 1–2$ PD), the metapostnotal rugae can vary from anastomosing to subparallel, sometimes not quite reaching the posterior margin, and the postgena can vary from shiny to lineate.

Range

Primarily Colorado Plateau with scattered records west to California (Fig. 29).

Lasioglossum (Dialictus) helianthi (Cockerell, 1916)

Figs 30–32, 76G, 106B, 107B, 109B, 110A, 115A

Halictus helianthi Cockerell, 1916: 77 (holotype, ♀, deposited in USNM, examined).

Lasioglossum (Dialictus) imbrex Gibbs, 2010: 153 (holotype, ♀, deposited in PCYU, examined).

Halictus (Chloralictus) helianthi – Michener 1936: 283 (male description).

Lasioglossum (Chloralictus) tegulariforme – Michener 1951: 1118 (in part, synonymy by Timberlake, catalogue).

Dialictus tegulariformis – Hurd 1979: 1929 (in part, catalogue). — Moure & Hurd 1987: 133 (in part, catalogue).

Lasioglossum (Dialictus) helianthi – Gardner & Gibbs 2022: 6 (resurrection from synonymy, synonymy with *L. imbrex*).

Diagnosis

Females of *L. helianthi* have the tegula relatively small (maximum length about half or less ITS and reaching but not exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin weakly concave and a posterior point usually narrower than 0.5 OD, and usually densely punctate ($IS \leq 1$ PD); mesoscutum finely, densely punctate ($IS \leq 1$ PD in posterior half and 4–5 punctures between posterior end of parapsidal line and lateral edge of mesoscutum) and entirely tessellate; metapostnotum with coarse anastomosing rugae reaching posterior margin; T1–T2 discs moderately densely and uniformly punctate ($IS = 1–2$ PD); T1 anterior slope usually coriarious; T3 usually with sparse tomentum throughout disc, paraocular area punctures larger and sparser than frons punctures; and gena narrower than eye in lateral view.

Females of *L. helianthi* are most similar to those of *L. angelicum* sp. nov., *L. ellisiae*, *L. gaudiale*, and *L. tegulariforme*, all of which (except *L. tegulariforme*) have T3 with tomentum limited to basolateral patches and, rarely, a sparse, medially interrupted subapical band. In addition, females of *L. angelicum* have the mesoscutum usually more coarsely or sparsely punctate ($IS = 1–2$ PD in posterior half and/or 2–3 punctures between posterior end of parapsidal line and lateral edge of mesoscutum), sometimes shiny,

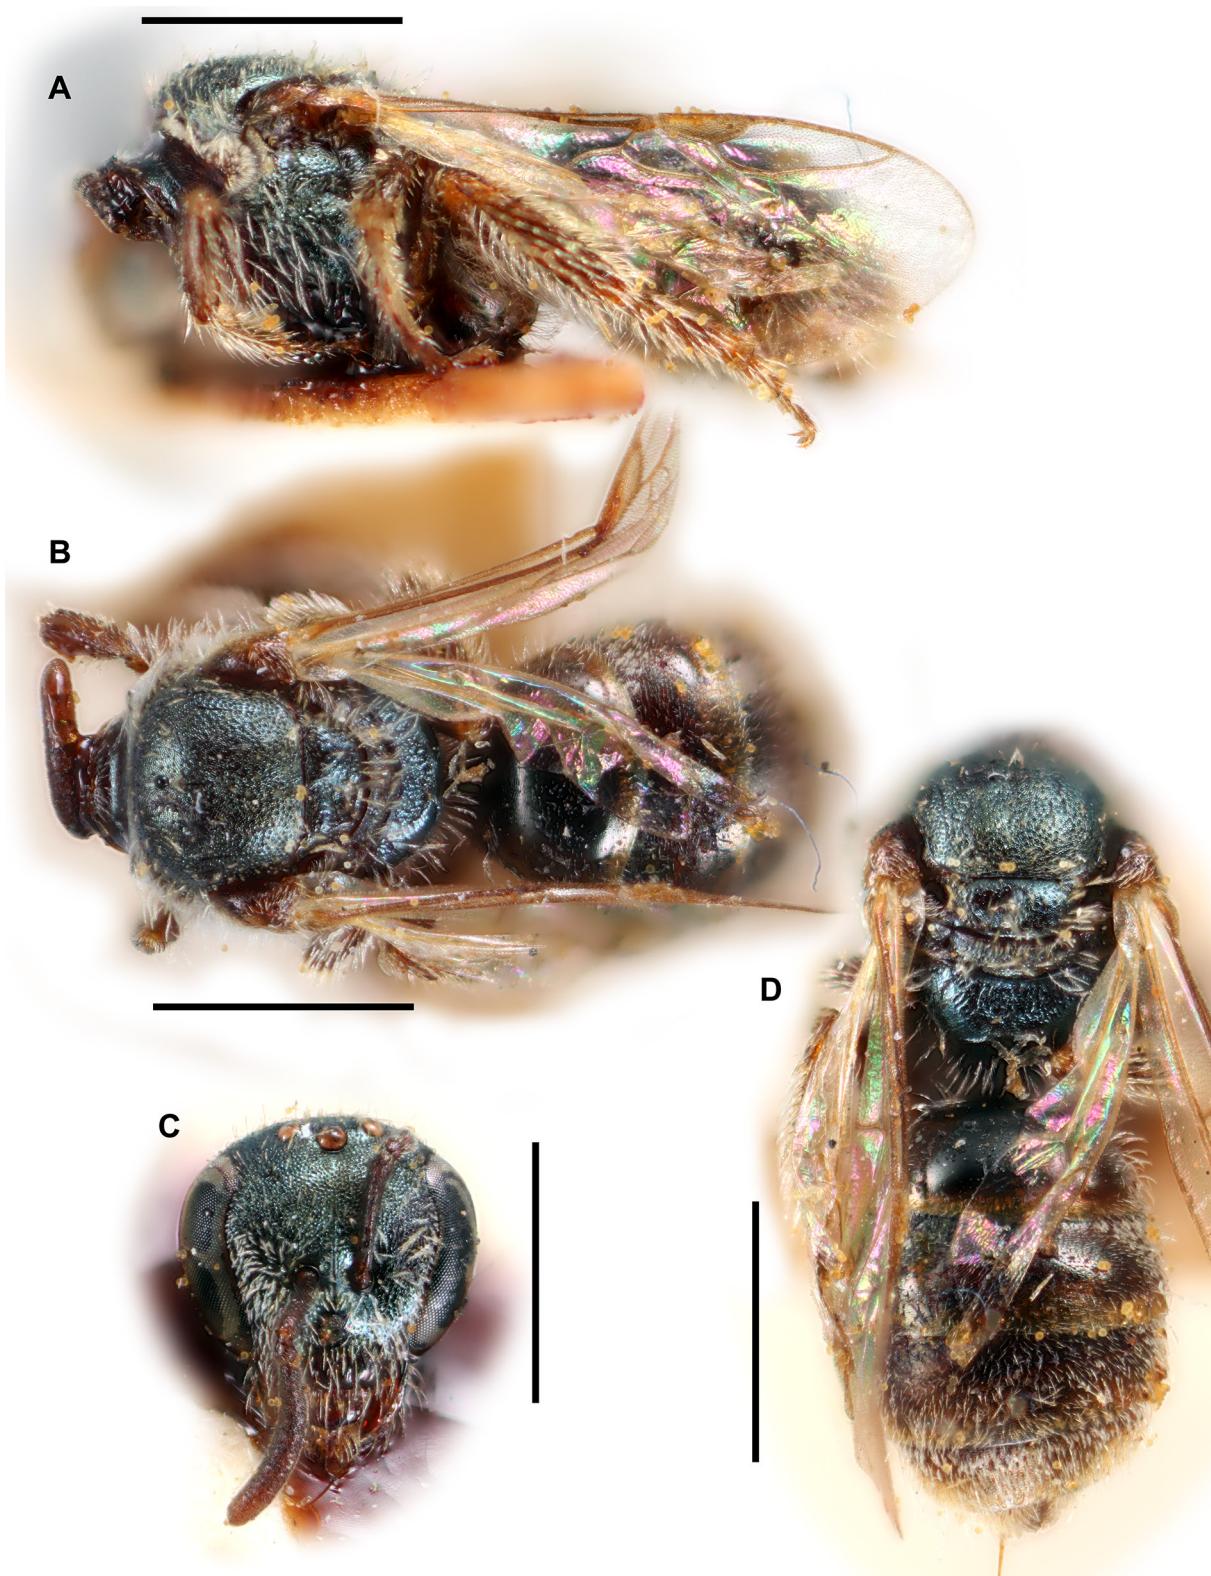

Fig. 30. *Lasioglossum (D.) helianthi* (Cockerell, 1916), ♀, holotype (USNM). **A.** Lateral habitus. **B.** Dorsal habitus. **C.** Face. **D.** Metasoma and propodeum. Scale bars = 1 mm.

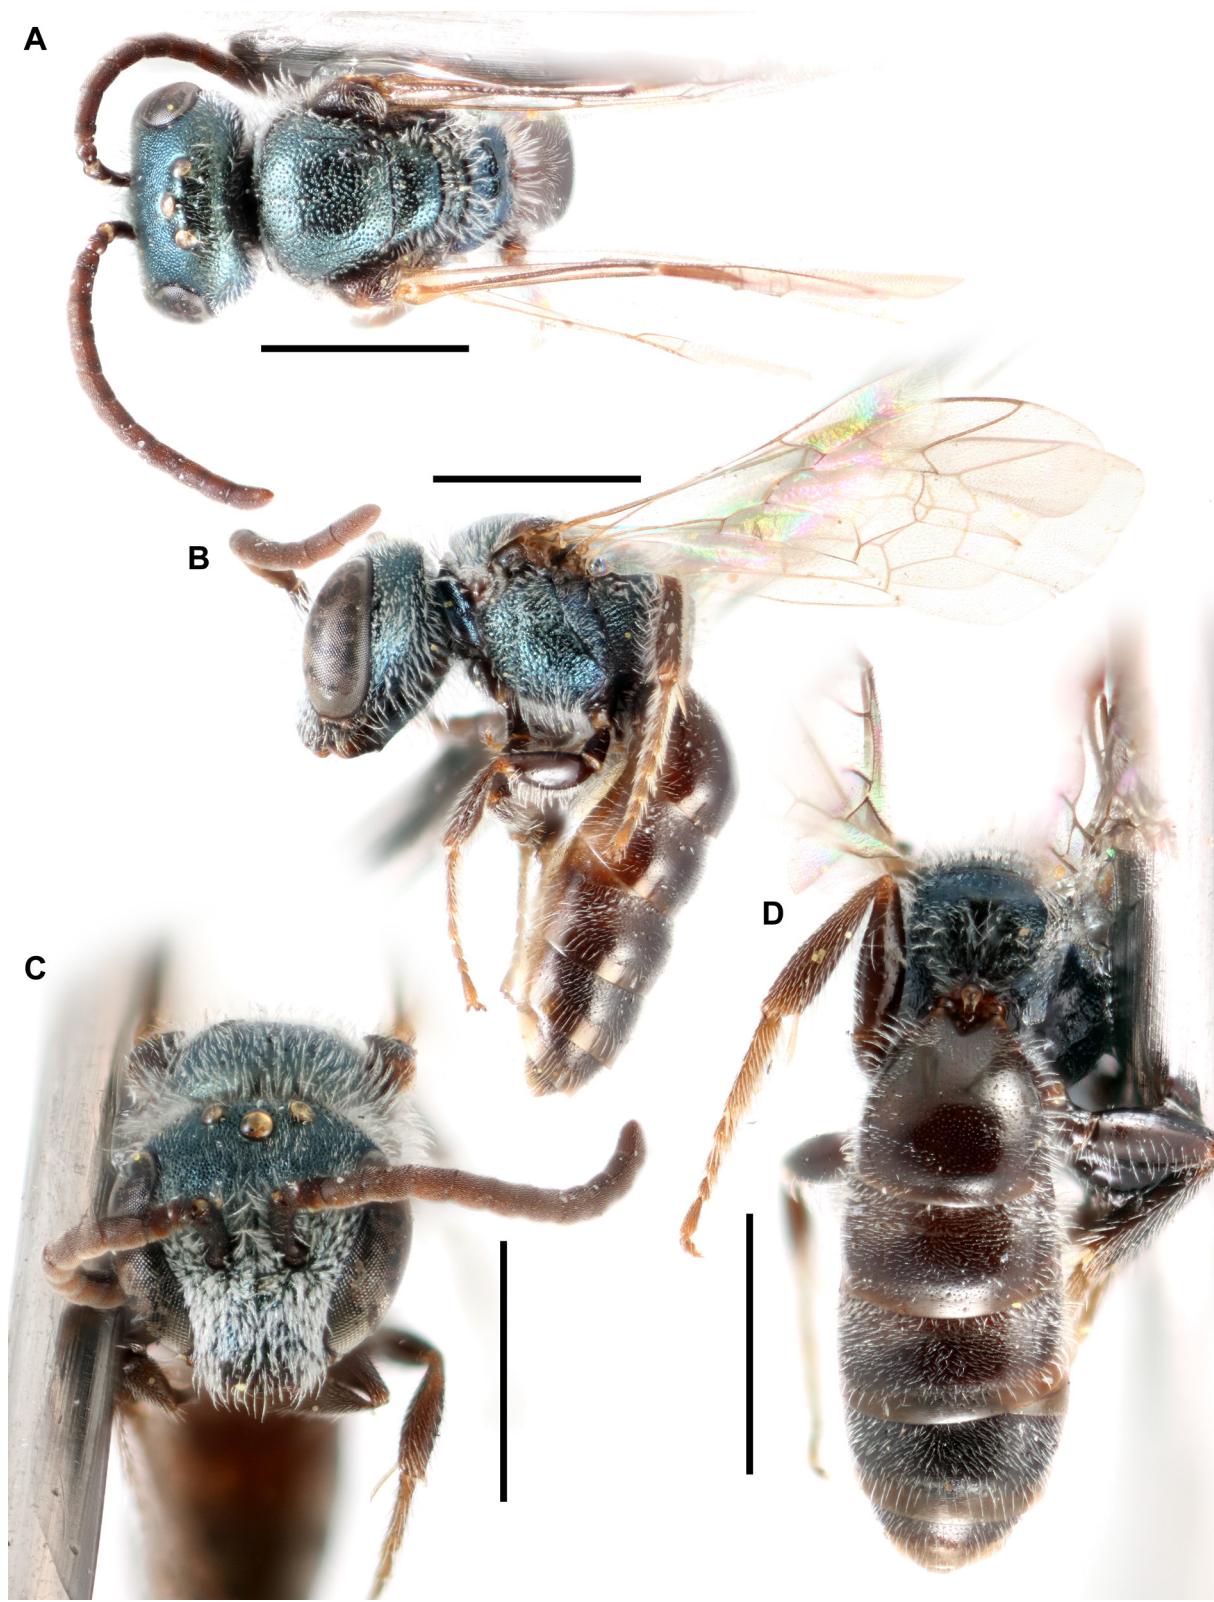

Fig. 31. *Lasioglossum (D.) helianthi* (Cockerell, 1916), ♂ (reproduced from Gardner & Gibbs 2022).
A. Dorsal habitus. **B.** Lateral habitus. **C.** Face. **D.** Metasoma and propodeum. Scale bars = 1 mm.

and tegula larger (maximum length more than half ITS and exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin strongly concave and a rounded posterior projection close to 1 lateral OD in size, and more densely punctate (IS < 1 PD). Females of *L. ellisiae* have the mesoscutum sometimes shiny posteriorly and slightly more sparsely punctate (most IS = 1 PD). Females of *L. gaudiale* have the mesoscutum more coarsely punctate (as in *L. angelicum*), T1 anterior slope shiny, and gena about as wide as eye in lateral view. Females of *L. tegulariforme* have the tegula larger and more densely punctate (as in *L. angelicum*), paraocular area punctures as large and dense as frons punctures, and T1 with an impunctate median line about 1 OD wide.

Males of *L. helianthi* have the tegula relatively small (as in the female); mesoscutum entirely densely punctate (IS < 1 PD); metapostnotum usually shiny with strong anastomosing rugae; and discs of T1–T2 deeply and moderately densely punctate (IS = 1–2 PD) with some punctures extending onto apical rims.

Males of *L. helianthi* are most similar to those of *L. angelicum* sp. nov., *L. diabolicum* sp. nov., *L. ellisiae*, and *L. tegulariforme*. Males of *L. angelicum* have the tegula larger (exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin strongly concave with a rounded posterior projection close to 1 lateral OD in size, and more densely punctate (IS < 1 PD); and mesoscutum usually more sparsely punctate (IS = 1–2 PD). Males of *L. diabolicum* have the discs of T1–T2 finely and moderately sparsely punctate (IS = 1–2 PD) and the mesoscutum usually more sparsely punctate (IS = 1–2 PD). Males of *L. ellisiae* have the T1–T2 apical rims impunctate and metapostnotum usually with subparallel rugae. Males of *L. tegulariforme* have the tegula larger (as in *L. angelicum*) and discs of T1–T2 (especially T1 medially) more sparsely punctate (IS = 1–3 PD).

Etymology

Cockerell (1916) named this species after the sunflowers it was collected on, *Helianthus lenticularis* Douglas ex Lindl. (= *Helianthus annuus* L.).

DNA barcodes

Ten confirmed sequences available (BOLD process IDs: DLII1375-08, DLII1400-08, DLII1416-08, DLII1518-08, DLIII143-19, DLIII144-19, DLIII145-19, BCLRB754-10, BCLRB755-10, BCLRB817-10). There is a small amount of divergence within these sequences (0.16% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. gaudiale* (1.07% minimum interspecific p-distance). One fixed nucleotide substitution distinguishes *L. helianthi* from all other Nearctic *L. gemmatum* complex species: 639(C) ([Supp. file 2](#)).

Comments

Lasioglossum imbrex was recorded from Alberta in Gibbs (2010), but all of the Alberta specimens were subsequently re-examined and determined as *L. stictaspis* in Gardner & Gibbs (2022). These specimens were not labelled as paratypes and it was not realised until after publication of Gardner & Gibbs (2022) that they were originally listed as such, and that the *L. imbrex* type series was mixed.

Lasioglossum (Dialictus) holzenthalii sp. nov.

[urn:lsid.zoobank.org/act:67961059-A459-4E63-9B7A-E519683BBCCA](https://lsid.zoobank.org/act:67961059-A459-4E63-9B7A-E519683BBCCA)

Figs 33–35, 76H, 81B, 95A, 96A, 97A, 102A, 116A

Diagnosis

Females of *L. holzenthalii* sp. nov. have the tegula very small (maximum length \leq 45% ITS and not reaching posterior margin of mesoscutum in dorsal view), with inner posterior margin straight or very

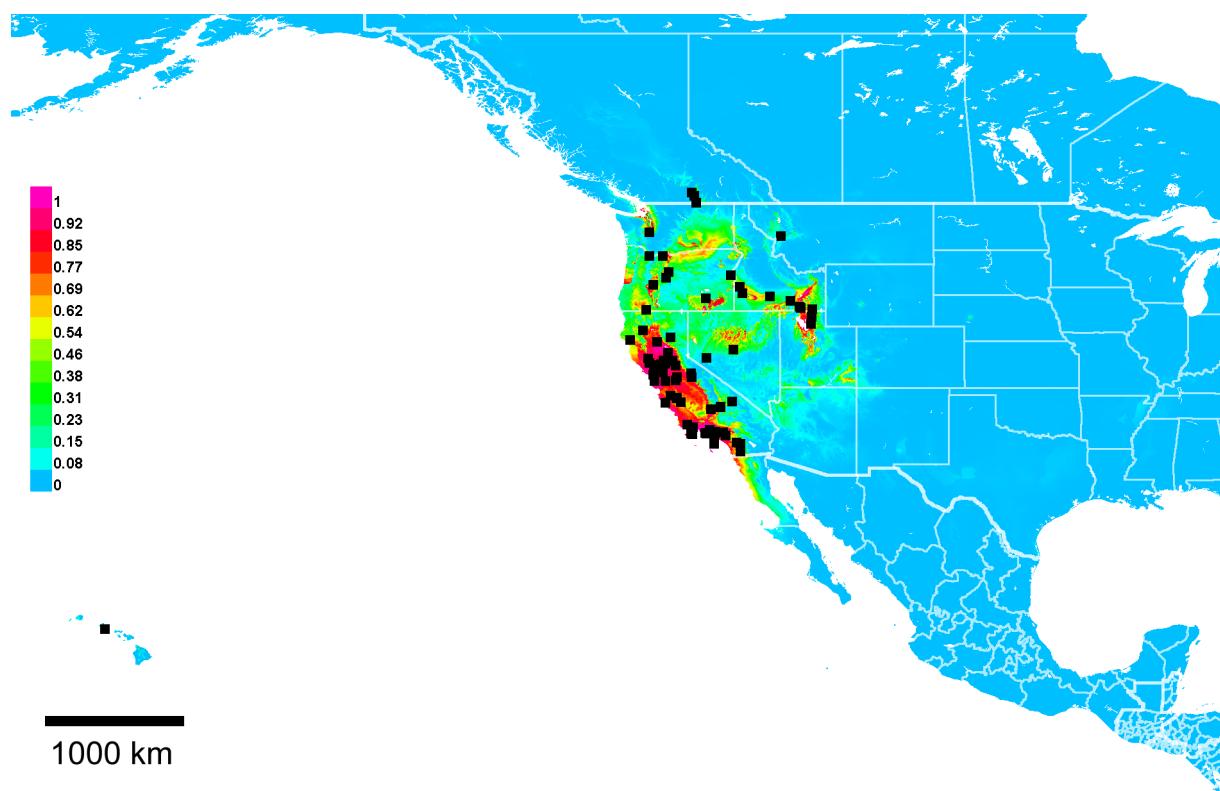

Fig. 32. Georeferenced collection records of *Lasioglossum (D.) helianthi* (Cockerell, 1916) (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

weakly concave, and usually sparsely punctate (IS = 1–4 PD); postgena smooth, shiny to imbricate; metapostnotum shiny with coarse subparallel rugae; mesepisternum very dull, strongly imbricate, with punctures dense but usually distinctly separated (IS ≤ 1 PD); T1–T3 apical rims usually distinctly punctate with very little change in sculpture across premarginal line; metasomal terga largely lacking tomentum (T2–T3 with very small basolateral patches and T4 with very sparse tomentum), and mesoscutum with dense erect pubescence (each seta less than its length from the one nearest it) and intervening setae short but with distinct length 0.25 OD or more.

Females of *L. holzenthalii* sp. nov. are most similar to those of *L. eremum* sp. nov., *L. perparvum*, and *L. profundum* sp. nov. Females of *L. perparvum* and *L. profundum* have the T1–T3 apical rims more sparsely or indistinctly punctate than discs or impunctate. Females of *L. eremum* have the mesoscutum and mesepisternum usually shiny and metapostnotum rugose with strong anastomosing rugae. Females of *L. perparvum* also have the metapostnotum dull with fine rugae and mesoscutum with sparse erect pubescence (each seta separated by about its length from the one nearest it) and intervening setae no more than stubble. Females of *L. profundum* have the tegula entirely impunctate (except anterior margin) and metasomal terga with more extensive tomentum.

Males of *L. holzenthalii* sp. nov. have the tegula relatively small (as in the female, but more often densely punctate (IS ≤ 1 PD)); T1–T3 uniformly densely punctate (IS ≤ 1 PD) with no change in sculpture across premarginal line; metapostnotum shiny with strong parallel rugae; and face below eye emargination with dense tomentum limited to lower paraocular area, sparse elsewhere. The densely punctate apical rims of T1–T3 are unique within the *L. gemmatum* species complex and will readily separate male *L. holzenthalii* from other known species. Males of *L. angelicum* sp. nov., *L. helianthi*, *L. pseudotegulare*, and some other species in the *L. stictaspis* species complex can have numerous punctures on the rims of T1–T2, but these punctures are absent on the extreme apical margins, T1 medially, and T2 far sides; in addition, the tegula is usually much larger with the inner posterior margin strongly concave.

Etymology

The specific epithet ‘*holzenthalii*’ is a dedication to Ralph Holzenthal, in recognition for kindling my interest in taxonomy and supporting my work and studies at UMSP.

Material examined

Description

Female

COLOURATION. Head and mesosoma blue-green to olive green; clypeus apex black; labrum black; mandible dark red with black basal spot and apex; flagellum black. Pronotal lobe black; legs black with tarsi dark reddish brown; tegula black to brown; wing membrane hyaline, veins with subcosta dark brown, otherwise lighter brown. Metasoma black with rims of terga and sterna narrowly translucent brown.

PUBESCENCE. Body pile colour white to pale yellow. Tomentum dense on pronotal collar and lobe and space between pronotal lobe and tegula; sparse on metepisternum, T2–T3 basolaterally, and T4 throughout. Mesoscutum pubescence thin to moderately plumose. Wing setae dark, short and dense. Acarinarial fan complete, sparse. T2 fringes sparse, T3 fringes sparse.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense in basal half ($IS \leq 1$ PD), large and irregularly sparse apically ($IS < 2$ PD); supraclypeal area imbricate, with punctures dense marginally ($IS \leq 1$ PD), sparser medially ($IS = 1–2$ PD); paraocular area imbricate, with punctures dense ($IS < 1$ PD), sparser around antenna socket ($IS \leq 1$ PD); frons reticulate, with punctures crowded ($IS = 0$ PD); vertex shiny, with punctures dense laterally ($IS < 1$ PD), fine and moderately sparse medially ($IS = 1–2$ PD); gena shiny, becoming lineolate posteriorly, with punctures absent; postgena shiny, becoming imbricate posteriorly. Tegula punctures fine, sparse ($IS = 1–4$ PD); mesoscutum tessellate, with punctures dense ($IS < 1$ PD), becoming sparse anteromedially ($IS = 1–3$ PD); scutellum tessellate, becoming shiny submedially, with punctures dense marginally ($IS < 1$ PD), moderately sparse submedially ($IS = 1–2$ PD); metapostnotum shiny, becoming weakly tessellate posteriorly, with rugae strong, subparallel, reaching posterior margin; preepisternum imbricate with crowded punctures ($IS = 0$ PD), becoming sparser and obscure ventrally ($IS = 1–2$ PD); hypoepimeron imbricate, with punctures dense ($IS < 1$ PD); mesepisternum imbricate, with punctures dense ($IS < 1$ PD), becoming moderately dense marginally ($IS = 1–2$ PD); metepisternum weakly rugulose; propodeum lateral surface weakly tessellate, posterior surface shiny. T1 anterior slope shiny, disc shiny, with punctures moderately dense ($IS = 1–2$ PD), absent in large subapical lateral boss; T2 disc shiny, with punctures moderately dense ($IS = 1–2$ PD), apical rim weakly cariarious, with punctures moderately sparse ($IS = 1–3$ PD).

STRUCTURE. Face length/width ratio 0.81 (± 0.01 SD); clypeus apicolateral denticles low rounded knobs; gena/eye width ratio 0.91 (± 0.09 SD). Pronotal angle slightly obtuse, nearly right-angled; intertegular span 0.97 (± 0.07 SD) mm; mesoscutum length/width ratio 0.87 (± 0.04 SD); mesoscutum/scutellum length ratio 2.89 (± 0.18 SD); scutellum/metanotum length ratio 1.8 (± 0.13 SD); metanotum/metapostnotum length ratio 0.71 (± 0.04 SD); forewing with 3 submarginal cells; tegula slightly enlarged, nearly reaching posterior margin of mesoscutum; inner margin straight; tegula length 0.4 (± 0.01 SD) mm, width 0.23 (± 0.01 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina weak, straight. T2 depressed apical rim less than 50% of tergum. (n = 10)

VARIATION. The tegula punctures can vary from very sparse ($IS = 1–4$ PD) to dense ($IS \leq 1$ PD), the mesepisternum punctures can vary from moderately sparse ($IS = 1–2$ PD) to dense ($IS < 1$ PD), and the T1–T3 apical rims can rarely be indistinctly punctate.

Male

COLOURATION. Head and mesosoma blue-green; clypeus apex black; labrum black; mandible orange with black base and red apex; flagellum black dorsally, brown ventrally. Pronotal lobe black; legs black to dark reddish brown; tegula dark brown; wing membrane lightly infuscated, veins with subcosta black, otherwise dark brown. Metasoma black with apical rims of terga narrowly translucent brown, apical rims of sterna and downcurved lateral areas of terga more broadly translucent brown.

PUBESCENCE. Body pile colour white. Tomentum dense on lower paraocular area, pronotal angle and lobe, and space between pronotal lobe and tegula; sparse on clypeus, supraclypeal area, and gena. Mesoscutum pubescence simple to moderately plumose. Wing setae dark, short and dense. Sterna pubescence short (0.5–1.5 OD), densely plumose, sparse on S_{2–3}, dense on S_{4–5}.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense (IS ≤ 1 PD); supraclypeal area imbricate, with punctures dense (IS ≤ 1 PD); paraocular area shiny, with punctures dense (IS < 1 PD); frons reticulate, with punctures crowded (IS = 0 PD); vertex shiny, with punctures dense (IS < 1 PD); gena shiny, with punctures dense (IS ≤ 1 PD); postgena shiny to lineate. Tegula punctures dense (IS < 1 PD), becoming moderately dense medially (IS = 1–2 PD); mesoscutum shiny, becoming tessellate anteromedially, with punctures moderately sparse (IS = 1–2 PD), becoming dense on lateral and posterior margins (IS < 1 PD); scutellum shiny to weakly tessellate, with punctures sparse (IS = 1–3 PD), diversopunctate, becoming dense marginally and on median line; metanotum weakly rugulose; metapostnotum shiny, with rugae strong, subparallel, nearly reaching posterior margin; preepisternum areolate; hypoepimeron shiny, with punctures dense (IS < 1 PD); mesepisternum shiny, with punctures dense (IS < 1 PD); metepisternum areolate, becoming smooth dorsally; propodeum lateral surface tessellate, with punctures crowded (IS = 0 PD), posterior surface shiny and densely punctate (IS < 1 PD). T1 anterior slope shiny, disc shiny, with punctures dense (IS ≤ 1 PD), becoming sparse in large subapicolateral boss (IS = 2–4 PD); T2 disc shiny, with punctures dense (IS ≤ 1 PD), apical rim shiny, with punctures dense (IS ≤ 1 PD).

STRUCTURE. Face length/width ratio 0.86 (±0.02 SD); gena/eye width ratio 0.74 (±0.08 SD). Pronotal angle obtuse; intertegular span 0.86 (±0.09 SD) mm; mesoscutum length/width ratio 0.87 (±0.02 SD); mesoscutum/scutellum length ratio 2.75 (±0.15 SD); scutellum/metanotum length ratio 1.83 (±0.19 SD); metanotum/metapostnotum length ratio 0.73 (±0.07 SD); forewing with 3 submarginal cells; tegula enlarged, nearly reaching posterior margin of mesoscutum in dorsal view; inner posterior margin weakly concave; tegula length 0.37 (±0.04 SD) mm, width 0.2 (±0.02 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina absent. (n = 10)

GENITALIA. As in Fig. 76H. Gonocoxite about 2 times as broad as gonostylus. Gonostylus very long, about 2 times as long as broad, and strongly concave on outer margin, with sparse long setae dorsally and on apical half of inner margin and short setae apically. Penis valves parallel, with sparse short setae laterally. Retrorse lobe rounded, about 2.7 times as long as broad, with sparse short setae in apical half.

VARIATION. The tegula punctures can vary from dense (IS ≤ 1 PD) and distinct to virtually impunctate, the mesoscutum can vary from mostly shiny to entirely tessellate, the scutellum punctures can vary from dense (IS < 1 PD) to sparse (IS = 1–3 PD), the metapostnotal rugae can vary from strong and nearly reaching the posterior margin to shallow and barely reaching halfway, and the apical rims of T1–T3 can be partially impunctate (but always with some punctures near the premarginal line). Most of this atypical variation was seen in a single, unusually small individual.

Range

Mountains of Texas, New Mexico, Arizona, and throughout Mexico (Fig. 35).

Floral hosts

APOCYNACEAE: *Asclepias* • ASPARAGACEAE: *Nolina* Michx.: *N. microcarpa* S.Watson • ASTERACEAE: *Bidens* L. • *Erigeron*: *E. oreophilus* Greenm. • FABACEAE: *Amorpha* L.: *A. fruticosa* L. • GERANIACEAE Juss.: *Geranium* L.: *G. caespitosum* E.James • ONAGRACEAE Juss.: *Lopezia* Cav.: *L. ciliatula* Plitmann, P.H.Raven & Breedlove [ambiguous] • PLANTAGINACEAE: *Penstemon*: *P. superbus* A.Nelson • RHAMNACEAE Juss.: *Ceanothus* L. • SCROPHULARIACEAE: *Scrophularia* L.: *S. parviflora* Wooton & Standl. • ZYGOPHYLLACEAE: *Kallstroemia* Scop.

DNA barcodes

Four confirmed sequences available (BOLD process IDs: BBLEG165-17, DLII1145-08, DLIII126-18, DLIII207-20). There is a moderate amount of divergence within these sequences (1.07% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. deludens* sp. nov. (2.01% minimum interspecific p-distance). No fixed nucleotide substitutions distinguish *L. holzenthalii* sp. nov. from all other species of the *L. gemmatum* complex, but four fixed nucleotide substitutions distinguish it from the closely related *L. perparvum* and all known related, undescribed Neotropical species: 120(C), 315(A), 477(T), and 499(C) ([Supp. file 2](#)).

Comments

Uncommon. *Lasioglossum holzenthalii* sp. nov. is regularly collected at high elevations in Mexico and the southern United States, but rarely in large numbers.

Fig. 35. Georeferenced collection records of *Lasioglossum(D.) holzenthalii* sp. nov. (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

***Lasioglossum (Dialictus) indagator* sp. nov.**

urn:lsid:zoobank.org:act:D5070EC1-B6A9-49D4-9C68-7D03A6BE5BCD

Figs 36–38, 76I, 84B, 105B

Diagnosis

Females of *L. indagator* sp. nov. have the tegula relatively small (reaching but not exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin weakly concave, with a gentle S-shaped curve and blunt posterior angle, and moderately sparsely punctate laterally at midlength (IS = 1–3 PD); mesoscutum lateral and posterior margins, metanotum, and pleura with abundant tomentum; mesoscutum, scutellum, and mesepisternum shiny and densely punctate (IS ≤ 1 PD) (mesoscutum becoming tessellate and more sparsely punctate anteromedially (IS = 1–2 PD)); metapostnotum with subparallel rugae not reaching posterior margin; T1 anterior slope coriaceous; gena subequal to or slightly wider than eye in lateral view; and tegula and metasoma red-orange.

Females of *L. indagator* sp. nov. are most similar to those of *L. diabolicum* sp. nov., *L. ellisiae*, *L. gaudiale*, and *L. gloriosum* sp. nov., all of which (except *L. gloriosum*) have the mesoscutum, metanotum, and pleura with tomentum sparse or absent, and all except *L. gaudiale* have the metapostnotum rugae reaching the posterior margin. In addition, females of *L. gaudiale* have the T1 anterior slope shiny and scutellum often sparsely punctate (IS = 1–2 PD). Females of *L. gloriosum* have the tegula larger (exceeding posterior margin of mesoscutum in dorsal view) and densely punctate (IS ≤ 1 PD). Females of *L. diabolicum* have the gena slightly narrower than the eye in lateral view.

Males of *L. indagator* sp. nov. have the tegula relatively small (at most slightly exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin weakly concave and a blunt posterior angle, and usually moderately sparsely punctate in part (IS = 1–2 PD); face broad (length/width ratio ≤ 0.83) and covered with very dense tomentum up to the median ocellus; mesoscutum usually moderately densely punctate (IS = 1–2 PD) and fringed with tomentum; pleura with extensive tomentum; metapostnotum shiny with strong, short rugae not reaching the posterior margin; T2–T3 with extensive basolateral tomentum; and head and mesosoma usually blue to blue-green. They are most similar to those of *L. gaudiale* and *L. gloriosum* sp. nov. See the diagnosis for *L. gaudiale* for a comparative diagnosis between these three species.

Etymology

The specific epithet ‘*indagator*’ is a noun derived from the Latin verb ‘*indago*’ (to hunt, chase) and the suffix ‘-ator’ (implying action or agency). It means ‘hunter’ and refers to the fact that most specimens were identified as *L. hunteri* in the past.

Description

Female

COLOURATION. Head and mesosoma blue-green to olive green; clypeus apex black; labrum black; mandible orange with black base and red apex; flagellum black dorsally, reddish brown ventrally. Pronotal lobe orange; legs brown; tegula orange; wing membrane hyaline, veins with subcosta dark brown, otherwise light brown to pale amber. Metasoma orange with dark spiracular spots on T2–T4 (small on T2) and rims of terga and sterna broadly translucent yellow.

PUBESCENCE. Body pile colour white. Tomentum dense on paraocular area, gena, pronotal collar and lobe, space between pronotal lobe and tegula, metanotum medially, metepisternum, and T2–T3 basolaterally; sparse on mesoscutum lateral and posterior margins, preepisternum, and T4. Mesoscutum pubescence moderately to densely plumose. Wing setae dark with light intermixed basally, short and dense. Acinarial fan complete, dense. T2 fringes sparse, T3 fringes sparse.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense in basal third ($IS \leq 1$ PD), large and irregularly spaced apically ($IS < 2$ PD); supraclypeal area shiny, with punctures dense marginally ($IS \leq 1$ PD), moderately dense medially ($IS = 1–2$ PD); paraocular area shiny, with punctures crowded ($IS = 0$ PD); frons shiny, with punctures crowded ($IS = 0$ PD); vertex shiny, with punctures dense laterally ($IS < 1$ PD), sparse medially ($IS = 1–3$ PD); gena shiny, with punctures fine, moderately dense ($IS = 1–2$ PD); postgena imbricate. Tegula punctures dense ($IS < 1$ PD), becoming sparse mediolaterally ($IS = 1–3$ PD); mesoscutum shiny, becoming tessellate anteromedially, with punctures dense ($IS < 1$ PD), becoming sparse anteromedially ($IS = 1–3$ PD); scutellum shiny, with punctures dense ($IS < 1$ PD); metapostnotum finely reticulate, with rugae weak, subparallel, not reaching posterior margin; preepisternum ruguloso-punctate; hypoepimeron shiny, with punctures crowded ($IS = 0$ PD); mesepisternum shiny, with punctures dense ($IS < 1$ PD); metepisternum lineolate; propodeum lateral surface tessellate, posterior surface weakly tessellate. T1 anterior slope coriarious, disc weakly coriarious, with punctures minute, moderately sparse ($IS = 1–3$ PD), absent on rim and in large subapical lateral boss; T2 disc weakly coriarious, with punctures minute, moderately dense ($IS = 1–3$ PD), apical rim weakly coriarious, with punctures minute, very sparse ($IS = 2–6$ PD), obscure.

STRUCTURE. Face length/width ratio 0.78 (± 0.02 SD); clypeus apicolateral denticles rounded obtuse points; gena/eye width ratio 0.9 (± 0.13 SD). Pronotal angle obtuse; intertegular span 0.77 (± 0.04 SD) mm; mesoscutum length/width ratio 0.9 (± 0.03 SD); mesoscutum/scutellum length ratio 2.85 (± 0.18 SD); scutellum/metanotum length ratio 1.74 (± 0.14 SD); metanotum/metapostnotum length ratio 0.84 (± 0.12 SD); forewing with 3 submarginal cells; tegula enlarged, reaching posterior margin of mesoscutum in dorsal view; inner posterior margin weakly concave; tegula length 0.41 (± 0.02 SD) mm, width 0.21 (± 0.01 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina very weak, straight. T2 depressed apical rim less than 50% of tergum. (n = 10)

VARIATION. The clypeus apical margin, labrum, and flagellum ventral surface can vary from black to orange, the mesoscutum and mesepisternum can vary from shiny to weakly tessellate or imbricate, and the metapostnotum microsculpture can vary from shiny to finely reticulate.

Male

COLOURATION. Head and mesosoma blue to blue-green; clypeus apex reddish brown; labrum orange; mandible orange with black basal spot and red apex; flagellum reddish brown dorsally, orange-brown

ventrally. Pronotal lobe orange-brown; legs reddish brown; tegula orange-brown; wing membrane hyaline, veins with subcosta brown, otherwise light brown. Metasoma black with depressed apical rims of terga and sterna translucent brown, downcurved lateral areas of terga becoming translucent yellow.

PUBESCENCE. Body pile colour white. Tomentum dense on face below lateral ocelli, gena, pronotal angle and lobe, space between pronotal lobe and tegula, metepisternum, and T2–T3 basally; sparse on scutum, preepisternum, mesepisternum, and T4 basally. Mesoscutum pubescence mostly densely plumose with sparse simple setae medially. Wing setae light with dark intermixed apically, short and sparse. Sterna pubescence short (0.5–1 OD), simple to moderately plumose, sparse.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense ($IS < 1$ PD); supraclypeal area shiny, with punctures dense ($IS \leq 1$ PD); paraocular area shiny, with punctures fine, dense ($IS < 1$ PD); frons shiny, with punctures fine, crowded ($IS = 0$ PD); vertex shiny, with punctures dense laterally ($IS < 1$ PD), moderately dense medially ($IS = 1–2$ PD); gena shiny, with punctures dense ($IS \leq 1$ PD); postgena shiny to lineate. Tegula punctures dense ($IS < 1$ PD), becoming moderately dense laterally ($IS = 1–2$ PD); mesoscutum shiny, with punctures moderately dense ($IS = 1–2$ PD); scutellum shiny, with punctures dense ($IS < 1$ PD); metanotum shiny and finely, densely punctate ($IS < 1$ PD) to rugulose; metapostnotum shiny to weakly tessellate, with rugae strong, subparallel, not reaching posterior margin; preepisternum areolate; hypoepimeron shiny, with punctures crowded ($IS = 0$ PD); mesepisternum shiny, with punctures dense ($IS < 1$ PD); metepisternum finely areolate, becoming smooth dorsally; propodeum lateral surface shiny to weakly tessellate, with punctures dense ($IS < 1$ PD), posterior surface shiny and densely punctate ($IS < 1$ PD). T1 anterior slope shiny, disc shiny, with punctures dense ($IS \leq 1$ PD), becoming moderately

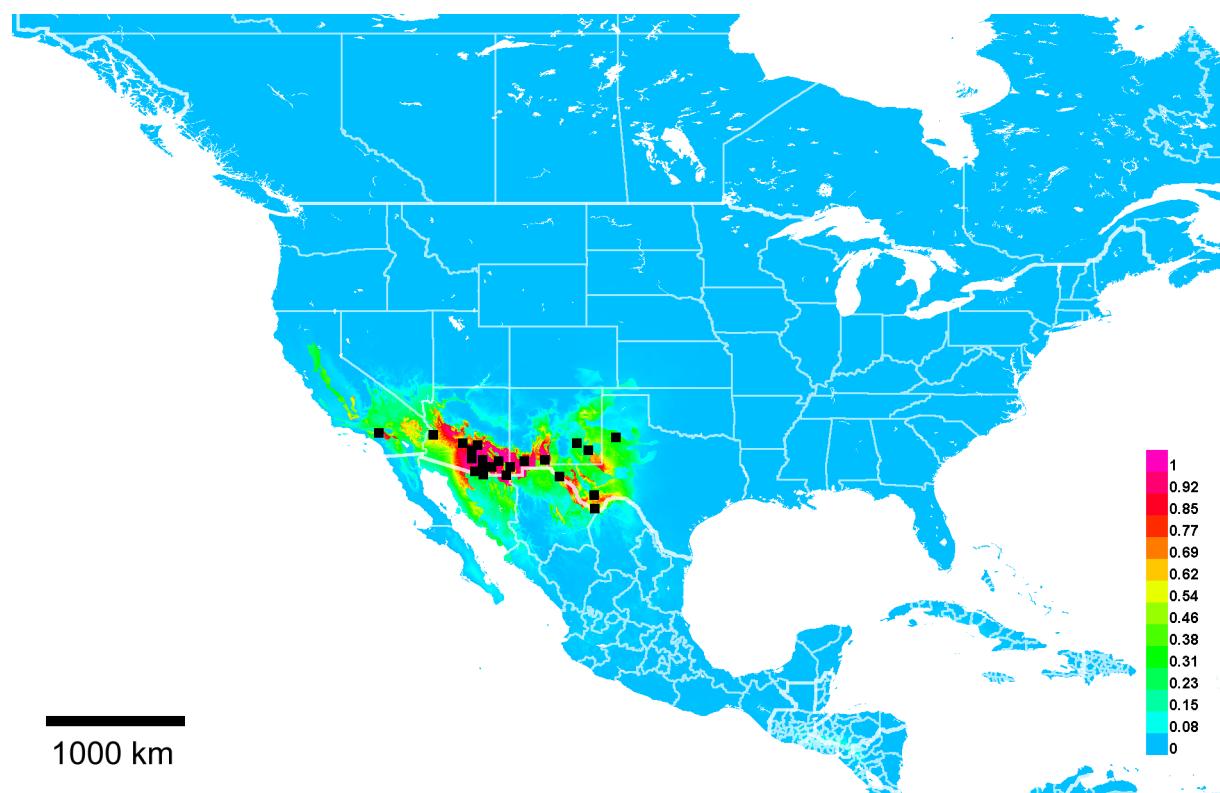

Fig. 38. Georeferenced collection records of *Lasioglossum (D.) indagator* sp. nov. (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

sparse laterally and on apical rim (IS = 1–2 PD), very sparse and fine in small subapicolateral boss (IS = 2–4 PD); T2 disc shiny, with punctures dense (IS ≤ 1 PD), apical rim shiny, with punctures absent.

STRUCTURE. Face length/width ratio 0.81 (± 0.43 SD); gena/eye width ratio 0.76 (± 0.4 SD). Pronotal angle obtuse; intertegular span 0.67 (± 0.04 SD) mm; mesoscutum length/width ratio 0.9 (± 0.47 SD); mesoscutum/scutellum length ratio 2.69 (± 1.42 SD); scutellum/metanotum length ratio 1.71 (± 0.17 SD); metanotum/metapostnotum length ratio 0.75 (± 0.4 SD); forewing with 3 submarginal cells; tegula enlarged, reaching posterior margin of mesoscutum in dorsal view; inner posterior margin weakly concave; tegula length 0.36 (± 0.03 SD) mm, width 0.2 (± 0.01 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina absent. (n = 9)

GENITALIA. As in Fig. 76I. Gonocoxite about 1.8 times as broad as gonostylus. Gonostylus rounded on outer margin with no concavities, with sparse long setae dorsally and in middle of inner margin, and short setae apically and along inner margin. Penis valves parallel, with sparse short setae laterally. Retorse lobe rounded, nearly 3 times as long as broad, with sparse short setae in apical half.

VARIATION. The metapostnotal rugae can occasionally reach the posterior margin, the terga punctures can vary from dense (IS ≤ 1 PD) to moderately dense (IS = 1–2 PD), and the tegula and pronotal lobe colour can vary from orange-brown to very dark brown.

Range

California and Sonoran and Chihuahuan Deserts (Fig. 38).

Floral hosts

ASTERACEAE: *Berlandiera* • BIGNONIACEAE: *Chilopsis* • BORAGINACEAE: *Phacelia* • EUPHORBIACEAE: *Euphorbia* • FABACEAE: *Medicago*: *M. sativa* • *Prosopis* • MALVACEAE: *Gossypium* • Sphaeralcea: *S. laxa* Wooton & Standl. • POLYGONACEAE: *Eriogonum*: *E. fasciculatum* • RHAMNACEAE: *Condalia* Cav. • SALICACEAE: *Salix* • SOLANACEAE: *Solanum*: *S. elaeagnifolium*.

DNA barcodes

Three confirmed sequences available (BOLD process IDs: BBHYA1505-12, DLII1076-07, DLIII123-18). There is a small amount of divergence within these sequences (0.15% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. helianthi* (1.4% minimum interspecific p-distance). One fixed nucleotide substitution distinguishes *L. indagator* sp. nov. from all other Nearctic *L. gemmatum* complex species: 315(G) ([Supp. file 2](#)).

Lasioglossum (Dialictus) lepidii (Graenicher, 1927)

Figs 39–41, 96B, 119A

Halictus (Chloralictus) lepidii Graenicher, 1927: 204 (holotype, ♀, deposited in USNM, examined).

Lasioglossum (Chloralictus) lepidii – Michener 1951: 1114 (catalogue).

Dialictus tegularis – Mitchell 1960: 423 (in part, synonymy, redescription). — Hurd 1979: 1972 (in part, catalogue). — Moure & Hurd 1987: 134 (in part, catalogue).

Lasioglossum (Dialictus) tegulare – Krombein 1967: 466 (in part, catalogue).

Lasioglossum (Dialictus) lepidii – Gibbs 2009a: 22 (resurrection from synonymy, redescription). — Gibbs 2011: 25, 32 (key to species), 130 (review).

Diagnosis

Females of *L. lepidii* have the tegula relatively small (reaching but not exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin straight and a blunt posterior angle, and sparsely punctate medially (IS = 1–3 PD); mesoscutum very dull, tessellate, and moderately densely punctate (IS = 1–2 PD) becoming dense on lateral and posterior margins (IS < 1 PD); metapostnotum with very strong, coarse rugae reaching posterior margin and covering propodeum dorsolateral slope; mesepisternum with weak microsculpture and dense, distinct punctures (IS < 1 PD); frons very finely punctate with very narrow, but distinct shiny interspaces between punctures; and T1–T3 very finely, minutely, obscurely punctate.

Females of *L. lepidii* are most similar to those of *L. ellisiae*, *L. holzenthalii* sp. nov., *L. puteulanum*, and *L. tegulare*. Females of *L. ellisiae* have the tegula inner posterior margin sinuous and pointed posteriorly, and mesoscutum often shiny posteriorly. Females of *L. holzenthalii* have the propodeum dorsolateral slope smooth, without rugae, and T1–T3 deeply and distinctly punctate. Females of *L. puteulanum* and *L. tegulare* have the mesepisternum very dull with crowded, indistinct punctures, and T1–T2 discs deeply and distinctly punctate.

Males of *L. lepidii* have the tegula relatively small (as in the female); metapostnotum shiny with strong anastomosing rugae; pleura finely and densely punctate (IS ≤ 1 PD), the preepisternum and hypoepimeral area more so than mesepisternum; discs of T1–T2 minutely and moderately sparsely punctate (IS = 1–2 PD) and apical rims impunctate; face with very dense appressed tomentum below eye emargination obscuring most of surface; and mesothoracic spiracle deeply impressed.

Males of *L. lepidii* are most similar to those of *L. diabolicum* sp. nov., *L. ellisiae*, *L. holzenthalii* sp. nov., *L. puteulanum*, and *L. tegulare*. All of these species have the preepisternum, hypoepimeral area, and mesepisternum more coarsely and uniformly punctate, mesothoracic spiracle no more deeply impressed than surrounding punctures, and facial tomentum either less dense or less tightly appressed, appearing shaggier. Males of *L. holzenthalii*, *L. puteulanum*, *L. tegulare*, and sometimes *L. ellisiae* have the disc of T2 more deeply and densely punctate (IS ≤ 1 PD). Males of *L. holzenthalii* also have the apical rims of T1–T3 deeply and densely punctate (IS ≤ 1 PD).

Many specimens from tropical regions of Mexico, from Veracruz to Yucatán to Jalisco, are very similar to those of *L. lepidii* both morphologically and in DNA barcodes. These specimens appear to have the mesoscutum more sparsely punctate laterally (IS = 1–2 PD) and metapostnotum with finer, shallow rugae.

Etymology

Graenicher (1927) named this species after the plant *Lepidium virginicum* L., one of its hosts.

DNA barcodes

Three confirmed sequences available (BOLD process IDs: DIAL863-06, DIAL865-06, DIAL867-06). There is a moderate amount of divergence within these sequences (0.61% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. pseudotegulare* in the Nearctic (2.06% minimum interspecific p-distance) and an undescribed species in the Neotropics (1.23% minimum interspecific p-distance). Two fixed nucleotide substitutions distinguish *L. lepidii* from all other Nearctic species of the *L. gemmatum* complex: 372(A) and 552(G) ([Supp. file 2](#)).

Comments

It is possible that additional work will determine some or all of the Neotropical specimens to be *L. lepidii*, but at present the great geographic distance between the two populations is taken as sufficient justification for keeping them separate. If *L. lepidii* occurs in Mexico, then it would also be expected to occur either in Cuba or the Gulf of Mexico coast between Florida and Veracruz, but no specimens resembling *L. lepidii* have been seen from these areas.

A record on BOLD from Hidden Valley Ranch RV Park, New Mexico, also has a very similar DNA barcode to *L. lepidii*, but the voucher specimen has not been examined. This location is very arid desert habitat, in stark contrast to the wet tropical or subtropical habitats of other specimens, and it would be very unusual for *L. lepidii* to regularly occur here.

Lasioglossum (Dialictus) magnitegula sp. nov.

[urn:lsid:zoobank.org:act:7F2257A4-B961-4C86-AFEC-ED2B2ECE27A5](https://doi.org/10.1545/zoobank.7F2257A4-B961-4C86-AFEC-ED2B2ECE27A5)

Figs 42–44, 76J, 78B, 79B, 80B, 113A

Diagnosis

Females of *L. magnitegula* sp. nov. have the tegula extremely large (maximum length \geq 60% ITS and clearly exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin strongly concave and a rounded posterior projection about 1 lateral OD in size, and very densely punctate (IS < 1 PD); metapostnotum very dull, finely reticulate, with fine subparallel rugae; metasomal terga apical rims shiny, glabrous, and impunctate; tomentum entirely absent on T4 disc and limited to small basolateral patches on T2–T3; mesoscutum with sparse erect pubescence less than 1 OD long (each seta about its length from the one nearest it) and very short intervening setae no more than stubble; and mesoscutum greenish, golden, or coppery, contrasting with bluer propodeum.

Females of *L. magnitegula* sp. nov. are most similar to those of *L. angelicum* sp. nov., *L. perparvum*, and *L. pseudotegulare*, all of which have the T4 disc with at least some sparse tomentum and metasomal terga apical rims with at least some minute punctures and/or short simple setae. All except *L. perparvum* have the mesoscutum with dense erect pubescence about 1 OD long (each seta less than its length from the one nearest it) and short intervening setae with a distinct length 0.25 OD or more. In addition, females of *L. angelicum* have the metapostnotum with coarse anastomosing rugae and basal half usually shiny, and *L. perparvum* have the tegula small (not exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin straight, and sparsely punctate (IS = 1–4 PD).

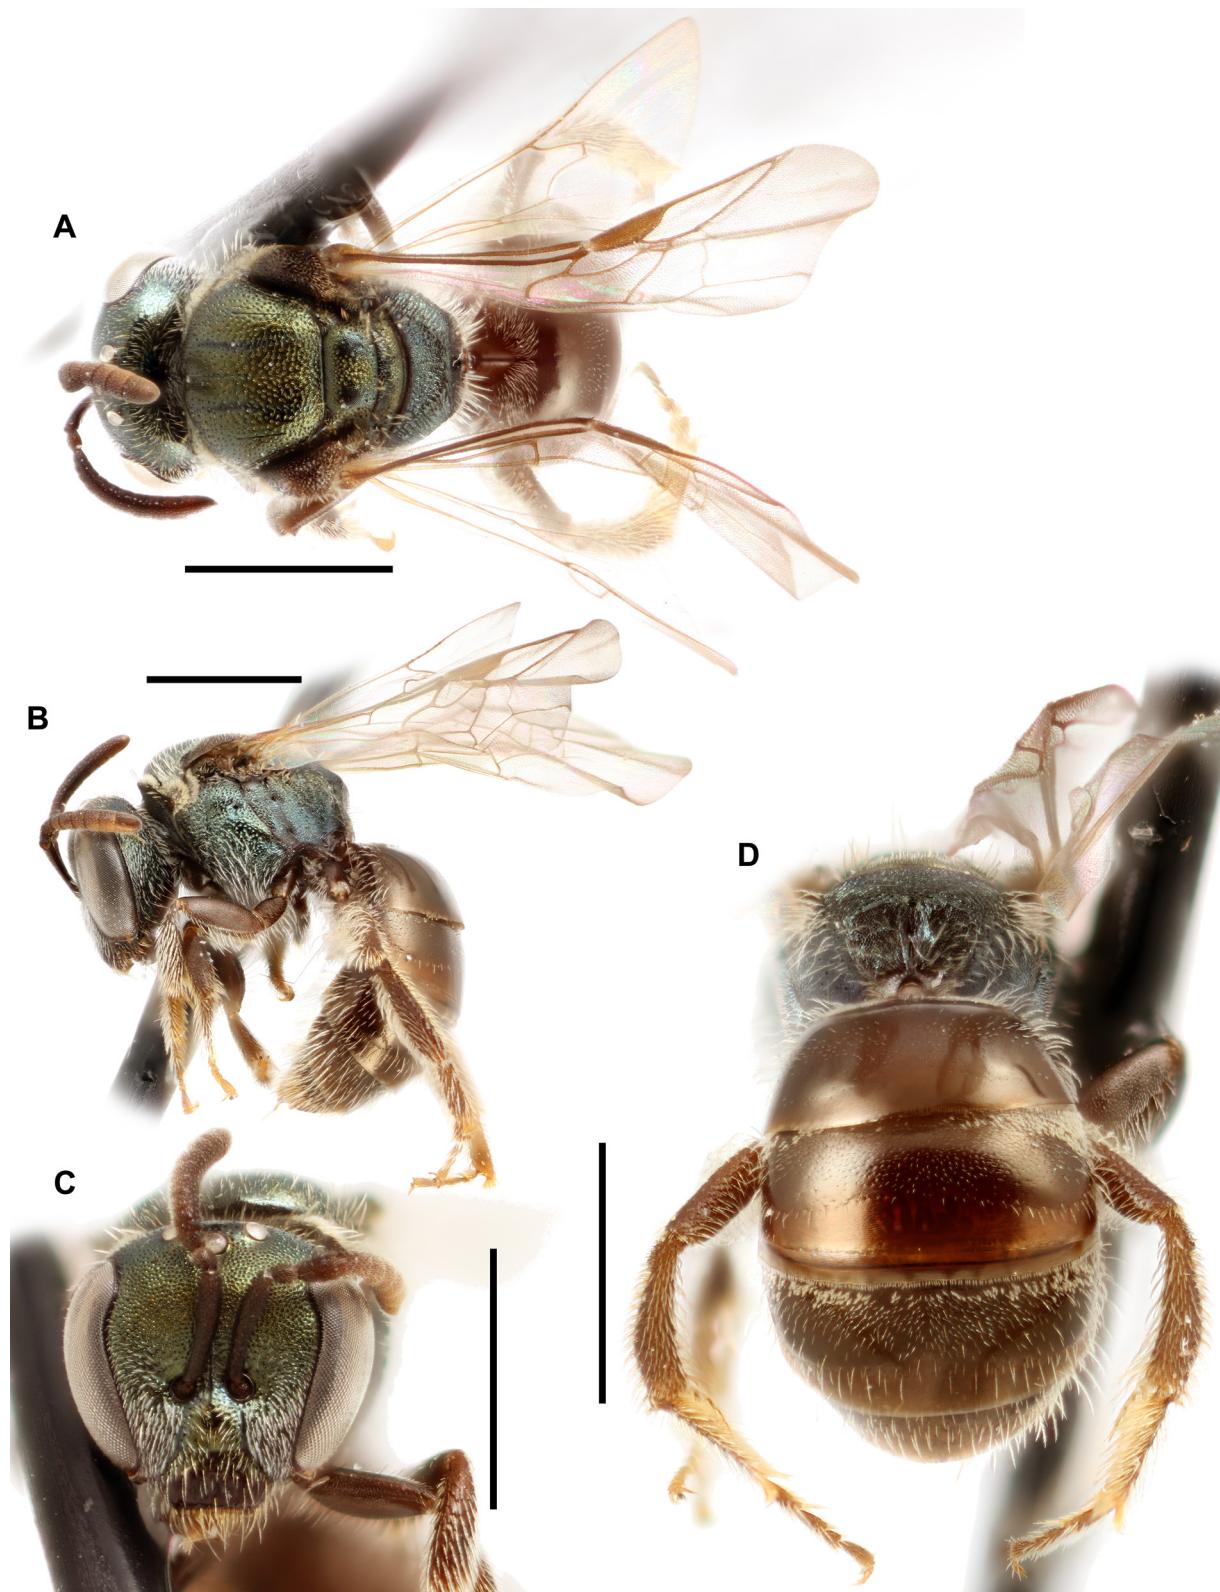

Fig. 42. *Lasioglossum (D.) magnitegula* sp. nov., ♀, holotype (BBSL FDP746586). A. Dorsal habitus. B. Lateral habitus. C. Face. D. Metasoma and propodeum. Scale bars = 1 mm.

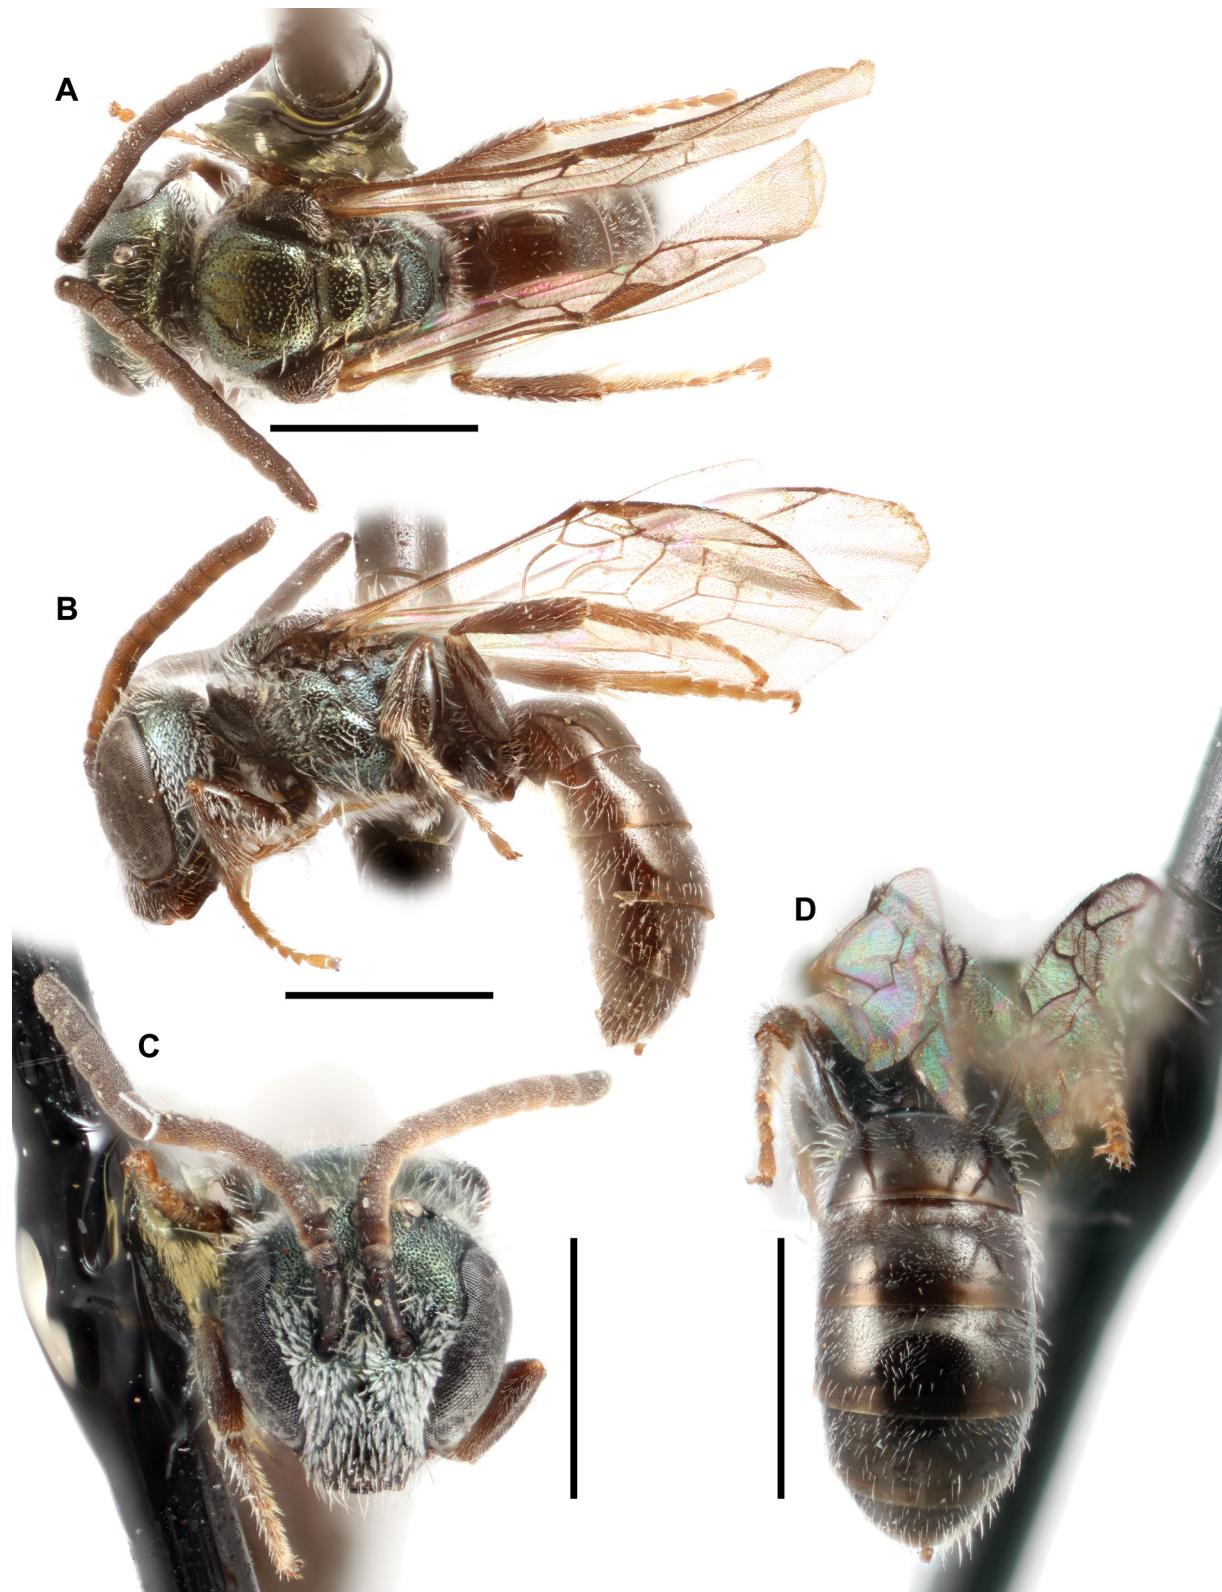

Fig. 43. *Lasioglossum (D.) magnitegula* sp. nov., ♂ (BBSL1101077). **A.** Dorsal habitus. **B.** Lateral habitus. **C.** Face. **D.** Metasoma. Scale bars = 1 mm.

Males of *L. magnitegula* sp. nov. have the tegula extremely large (as in the female); mesoscutum usually shiny and coarsely, moderately sparsely punctate (IS = 1–2 PD), with sparse erect pubescence (some gaps 0.5 OD or wider visible in lateral view) appearing simple at 40 × magnification, and more greenish or golden, contrasting with bluer propodeum; metapostnotum tessellate to reticulate with fine subparallel rugae; T1–T2 apical rims and discs apicolaterally impunctate or very minutely, sparsely punctate; and face relatively long (length/width ratio usually >0.86).

Males of *L. magnitegula* sp. nov. are most similar to those of *L. angelicum* sp. nov., *L. perparvum*, and *L. pseudotegulare*. Males of *L. angelicum* and *L. pseudotegulare* have the T1–T2 apical rims punctate, mesoscutum with dense erect, plumose pubescence (no gaps wider than 0.5 OD visible in lateral view), and mesoscutum concolourous with the rest of the mesosoma. In addition, males of *L. angelicum* have the face slightly shorter (length/width ratio ≤0.86). Males of *L. perparvum* have the tegula much smaller (not exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin weakly concave, and sparsely punctate laterally (IS = 1–3 PD); and mesoscutum usually tessellate and finely, densely punctate laterally (IS <1 PD).

Etymology

The specific epithet ‘*magnitegula*’ is a noun derived from the Latin adjective ‘*magnus*’ (large, great) and the noun ‘*tegula*’ (roof tile, literally ‘covering instrument’, now applied to the sclerite covering the wing base). It refers to the extraordinarily enlarged tegula of this species relative to its small body size. An appropriate translation would be the big-tegula sweat bee.

Description

Female

COLOURATION. Head and mesosoma blue-green to golden-green; clypeus apex black; labrum brown; mandible brown with black base and red apex; flagellum dark brown dorsally, lighter brown ventrally. Pronotal lobe black; legs black to dark brown; tegula dark brown; wing membrane lightly infuscated, veins dark brown. Metasoma black with rims of terga and sterna broadly brown.

PUBESCENCE. Body pile colour white to pale yellow. Tomentum dense on pronotal collar and lobe, space between pronotal lobe and tegula, and T2–T3 basal margins; sparse on lower paraocular area and gena. Mesoscutum pubescence thin, weakly plumose. Wing setae dark, short and dense. Acinarial fan complete, dense. T2 fringes absent, T3 fringes absent.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense ($IS \leq 1$ PD); supraclypeal area shiny, with punctures dense ($IS \leq 1$ PD); paraocular area imbricate around antenna socket, otherwise shiny, with punctures crowded ($IS = 0$ PD); frons reticulate, with punctures crowded ($IS = 0$ PD); vertex shiny, with punctures crowded laterally ($IS = 0$ PD), sparse medially ($IS = 1-2$ PD); gena lineolate, with punctures minute, dense ($IS \leq 1$ PD), obscure; postgena lineolate. Tegula punctures crowded ($IS = 0$ PD); mesoscutum tessellate, with punctures dense ($IS < 1$ PD), becoming moderately sparse anteromedially ($IS = 1-2$ PD); scutellum tessellate, with punctures dense marginally and on median line ($IS < 1$ PD), absent submedially; metapostnotum finely reticulate, with rugae weak, subparallel, reaching posterior margin; preepisternum rugose; hypoepimeron imbricate, with punctures crowded ($IS = 0$ PD); mesepisternum imbricate, with punctures dense ($IS \leq 1$ PD); metepisternum lineate dorsally, imbricate ventrally; propodeum lateral surface tessellate, posterior surface tessellate. T1 anterior slope weakly coriarious, disc weakly coriarious, with punctures fine, sparse ($IS = 1-4$ PD), absent in large subapicalateral boss and on rim; T2 disc weakly coriarious, with punctures fine, moderately sparse ($IS = 1-3$ PD), apical rim weakly coriarious, with punctures absent.

STRUCTURE. Face length/width ratio 0.83 (± 0.01 SD); clypeus apicolateral denticles low rounded knobs; gena/eye width ratio 0.84 (± 0.09 SD). Pronotal angle obtuse; intertegular span 0.73 (± 0.04 SD) mm; mesoscutum length/width ratio 0.95 (± 0.04 SD); mesoscutum/scutellum length ratio 2.8 (± 0.16 SD); scutellum/metanotum length ratio 1.87 (± 0.19 SD); metanotum/metapostnotum length ratio 0.75 (± 0.08 SD); forewing with 3 submarginal cells; tegula enlarged, exceeding posterior margin of mesoscutum in dorsal view; inner posterior margin strongly concave, with broadly rounded projection angled toward axilla posteriorly; tegula length 0.46 (± 0.03 SD) mm, width 0.22 (± 0.02 SD) mm; propodeum lateral carinae nearly reaching dorsal margin; oblique carina strong, straight. T2 depressed apical rim less than 50% of tergum. ($n = 10$)

VARIATION. The mesoscutum and mesepisternum can vary from shiny to dull and densely punctate ($IS < 1$ PD) to moderately sparsely punctate ($IS = 1-2$ PD); the metasomal terga discs can vary from distinctly punctate to nearly impunctate; and T2–T3 sometimes lack any tomentum, even basolaterally.

Male

COLOURATION. Head and mesosoma blue-green to golden green; clypeus apex black; labrum black; mandible orange with black base and red apex; flagellum black dorsally, brown ventrally. Pronotal lobe black; legs dark brown; tegula black to dark reddish brown; wing membrane infuscated, veins with subcosta black, otherwise dark brown. Metasoma black with depressed apical rims of terga and sterna and downcurved lateral areas of terga translucent brown.

PUBESCENCE. Body pile colour white. Tomentum dense on lower paraocular area, pronotal angle and lobe, and space between pronotal lobe and tegula; sparse on clypeus, supraclypeal area, and gena. Mesoscutum pubescence simple. Wing setae dark, long and dense. Sterna pubescence short (0.5–1.5 OD), moderately plumose, sparse.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense ($IS \leq 1$ PD); supraclypeal area shiny to weakly imbricate, with punctures dense ($IS \leq 1$ PD); paraocular area shiny, with punctures dense ($IS < 1$ PD); frons reticulate, with punctures crowded ($IS = 0$ PD); vertex shiny, with punctures dense laterally ($IS < 1$ PD), slightly sparser medially ($IS \leq 1.5$ PD); gena shiny anteriorly, lineate posteriorly, with punctures fine, moderately dense ($IS = 1-2$ PD), obscure; postgena shiny to lineate. Tegula punctures crowded ($IS = 0$ PD); mesoscutum shiny, with punctures moderately sparse ($IS = 1-2$ PD), becoming dense on lateral and posterior margins ($IS < 1$ PD); scutellum shiny, with punctures moderately sparse ($IS = 1-2$ PD); metanotum shiny with fine crowded punctures ($IS = 0$ PD); metapostnotum tessellate to finely reticulate, with rugae shallow, subparallel, nearly reaching posterior margin; preepisternum areolate; hypoepimeron shiny, with punctures crowded ($IS = 0$ PD); mesepisternum shiny, with punctures dense ($IS < 1$ PD);

metepisternum finely rugulose, becoming smooth dorsally; propodeum lateral surface shiny to imbricate, with punctures dense ($IS \leq 1$ PD), shallow and obscure, posterior surface shiny and obscurely, densely punctate ($IS \leq 1$ PD). T1 anterior slope shiny, disc shiny, with punctures fine, sparse ($IS = 1–3$ PD), absent in large subapicolateral boss and on rim; T2 disc shiny, with punctures fine, sparse ($IS = 1–3$ PD), apical rim shiny, with punctures absent.

STRUCTURE. Face length/width ratio 0.87 (± 0.01 SD); gena/eye width ratio 0.7 (± 0.07 SD). Pronotal angle obtuse; intertegular span 0.62 (± 0.05 SD) mm; mesoscutum length/width ratio 0.99 (± 0.05 SD); mesoscutum/scutellum length ratio 2.62 (± 0.22 SD); scutellum/metanotum length ratio 1.95 (± 0.31 SD); metanotum/metapostnotum length ratio 0.73 (± 0.08 SD); forewing with 3 submarginal cells; tegula enlarged, exceeding posterior margin of mesoscutum in dorsal view; inner posterior margin strongly concave, with broadly rounded projection angled toward axilla posteriorly; tegula length 0.45 (± 0.03 SD) mm, width 0.21 (± 0.02 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina absent. (n = 10)

GENITALIA. As in Fig. 76J. Gonocoxite about 2 times as broad as gonostylus. Gonostylus short, slightly longer than broad, and slightly concave on outer margin, without long setae. Penis valves parallel, with sparse short setae laterally. Retrorse lobe rounded, about 2.8 times as long as broad, with sparse short setae in median band.

VARIATION. The mesoscutum and scutellum punctures can vary from dense ($IS < 1$ PD) to sparse ($IS = 1–3$ PD), the mesoscutum can sometimes be tessellate anteromedially, the meseepisternum punctures can vary from dense ($IS < 1$ PD) to moderately dense ($IS = 1–2$ PD), and the terga punctures can vary from deep and distinct to so minute that they are hardly visible.

Fig. 44. Georeferenced collection records of *Lasioglossum (D.) magnitegula* sp. nov. (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

Range

Western Mexico from Sonora to Chiapas, crossing into Veracruz at the Isthmus of Tehuantepec (Fig. 44).

Floral hosts

PLANTAGINACEAE: *Bacopa* Aubl. • VERBENACEAE: *Phyla* Lour.: *P. nodiflora* (L.) Greene.

DNA barcodes

None available.

Comments

Common in Mexico. *Lasioglossum magnitegula* sp. nov. probably occurs rarely in the United States. Four specimens were collected from Rancho San Bernardino, Sonora, less than 2 km from the US border.

Lasioglossum (Dialictus) paululum (Sandhouse, 1924)

Halictus (Chloralictus) paululus Sandhouse, 1924: 23 (holotype, ♂, deposited in USNM, type no. 26419, USNMENT01570300, examined).

Lasioglossum (Chloralictus) paululum – Michener 1951: 1116 (catalogue).

Dialictus paululus – Hurd 1979: 1969 (catalogue). — Moure & Hurd 1987: 120 (catalogue).

Lasioglossum (Dialictus) paululum – Scott *et al.* 2011: 30 (checklist).

Diagnosis

See the diagnosis for the *L. stictaspis* species complex. *Lasioglossum paululum* is a member of this group and reliable, unique diagnostic characters are not yet known. Female specimens determined as *L. stictaspis* from Colorado, which may correspond to *L. paululum*, frequently have the mesoscutum and mesepisternum shiny, T3 with very dense and complete subapical band of tomentum, ocellular area shiny with distinctly separated punctures ($IS \leq 1$ PD), and all pubescence bright white, in contrast with specimens from New Mexico which usually have the mesoscutum and mesepisternum dull, T3 with subapical band of tomentum slightly sparser and narrowly interrupted medially, ocellular area dull with crowded punctures ($IS = 0$ PD), and pubescence yellowish dorsally. However, the dull New Mexico forms can occur as far north as Alberta, and the shiny Colorado forms can occur west to Arizona, with any combination of these characters possible in between. The males are even more difficult to separate, but male *L. paululum* may have a slightly longer face. Sandhouse (1924) described the face as relatively long, although the holotype length/width ratio is only 0.84.

Comments

Lasioglossum paululum may be a junior synonym of *L. stictaspis*, but a more detailed revision of the *L. stictaspis* species complex is needed. If *L. paululum* proves to be distinct, then at least some of the *L. stictaspis* specimens recorded from Canada in Gardner & Gibbs (2022) are probably this species.

Lasioglossum (Dialictus) perparvum (Ellis, 1914)

Figs 45–47, 76K, 78A, 79A, 80A, 115B, 116B

Halictus perparvus Ellis, 1914: 102 (holotype, ♀, deposited in USNM, examined).

Halictus pseudotegularis non auct. – Cockerell 1898: 237 (comparison to *tegulare*).

Halictus perparvus – Cockerell 1916: 77 (comparative notes to *helianthi*).

Halictus (Chloralictus) perparvus – Sandhouse 1924: 2 (key to species), 12 (comparison to *ellisiae*).

Lasioglossum (Chloralictus) perparvum – Michener 1951: 1116 (catalogue).

Dialictus perparvus – Hurd 1979: 1970 (catalogue). — Moure & Hurd 1987: 121 (catalogue).

Diagnosis

Females of *L. perparvum* have the tegula relatively small (reaching but not exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin straight and a blunt posterior angle, and finely, sparsely punctate laterally (IS = 1–4 PD); mesoscutum densely punctate (IS < 1 PD, becoming sparser (IS = 1–2 PD) anteromedially); metapostnotum very dull, finely reticulate, with fine subparallel rugae; T2 apical rim with scattered minute punctures bearing short simple setae; T4 disc with sparse tomentum; mesoscutum with sparse erect pubescence (each seta separated by about its length from the one nearest it and some gaps more than 0.5 OD visible in lateral view) and very short intervening setae no more than stubble; and mesoscutum greenish or golden, contrasting with bluer propodeum.

Females of *L. perparvum* are most similar to those of *L. holzenthali* sp. nov., *L. lepidii*, *L. magnitegula* sp. nov., and *L. profundum* sp. nov., all of which (except *L. magnitegula*) have the mesoscutum with denser erect pubescence (each seta separated by less than its length from the one nearest it and no gaps more than 0.5 OD visible in lateral view) with short intervening setae 0.25 OD long or more, mesoscutum concolourous with propodeum, and metapostnotum shiny with weak microsculpture and strong, coarse rugae. In addition, females of *L. holzenthali* have the T1–T3 apical rims usually deeply and distinctly punctate and *L. profundum* have the tegula entirely impunctate except on anterior margin. Females of *L. magnitegula* have the tegula much larger (clearly exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin strongly concave, and densely punctate (IS < 1 PD), T2 apical rim glabrous and impunctate, and T4 disc lacking tomentum.

Males of *L. perparvum* have the tegula relatively small (as in the female); mesoscutum tessellate anteriorly and densely punctate laterally (IS < 1 PD), with sparse erect pubescence (some gaps 0.5 OD or more visible in lateral view); metapostnotum tessellate to finely reticulate with fine subparallel rugae; discs of T1–T2 deeply and moderately densely punctate (IS = 1–2 PD); and mesoscutum more greenish or golden, contrasting with bluer propodeum.

Males of *L. perparvum* are most similar to those of *L. diabolicum* sp. nov., *L. ellisiae*, and *L. magnitegula* sp. nov. Males of *L. diabolicum* and *L. ellisiae* have the mesoscutum usually shiny, concolourous with the rest of the mesosoma, and with dense erect pubescence (no gaps more than 0.5 OD visible in lateral view). Males of *L. magnitegula* have the tegula much larger (exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin strongly concave, and densely punctate (IS < 1 PD); and mesoscutum usually shiny and more coarsely punctate laterally (IS ≤ 1 PD).

In the Neotropics there are at least two (but possibly more) very similar, undescribed species. One of these has the tegula more coarsely and densely punctate laterally (IS < 1 PD); the other has the mesoscutum with sparser punctures laterad of the parapsidal line (IS ≥ 1 PD) and T2 apical rim impunctate and glabrous in the female.

Lasioglossum deludens sp. nov. is not especially similar to those of *L. perparvum*, but has been very often misidentified as *L. perparvum* and it is worth diagnosing the two specifically. Both sexes of *L. deludens* have the tegula translucent yellow-orange and impunctate (except on anterior margin) (opaque brown and punctate in *L. perparvum*), mesoscutum with dense erect pubescence (sparse in *L. perparvum*) and concolourous with propodeum (propodeum distinctly bluer in *L. perparvum*), and metapostnotum shiny with strong, coarse rugae (dull with fine rugae in *L. perparvum*). Females have the mesoscutum usually

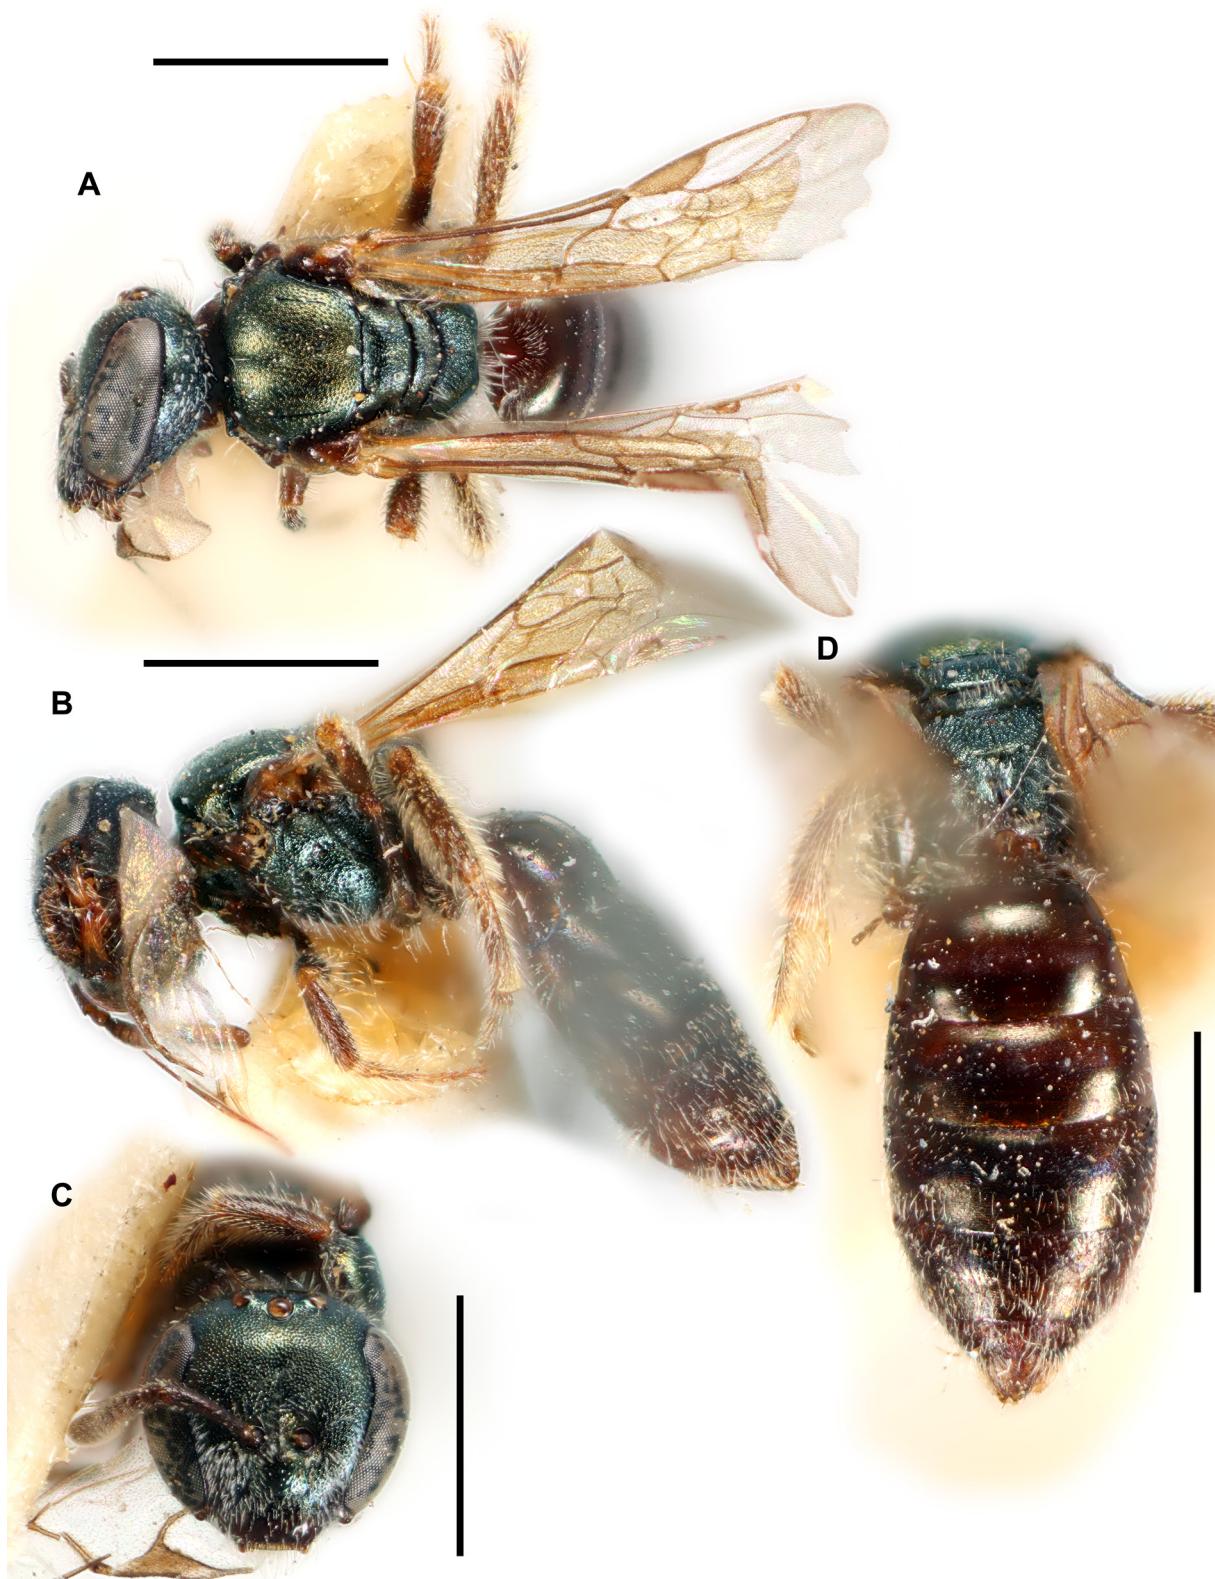

Fig. 45. *Lasioglossum (D.) perparvum* (Ellis, 1914), ♀, holotype (USNM). **A.** Dorsal habitus. **B.** Lateral habitus. **C.** Face. **D.** Metasoma and propodeum. Scale bars = 1 mm.

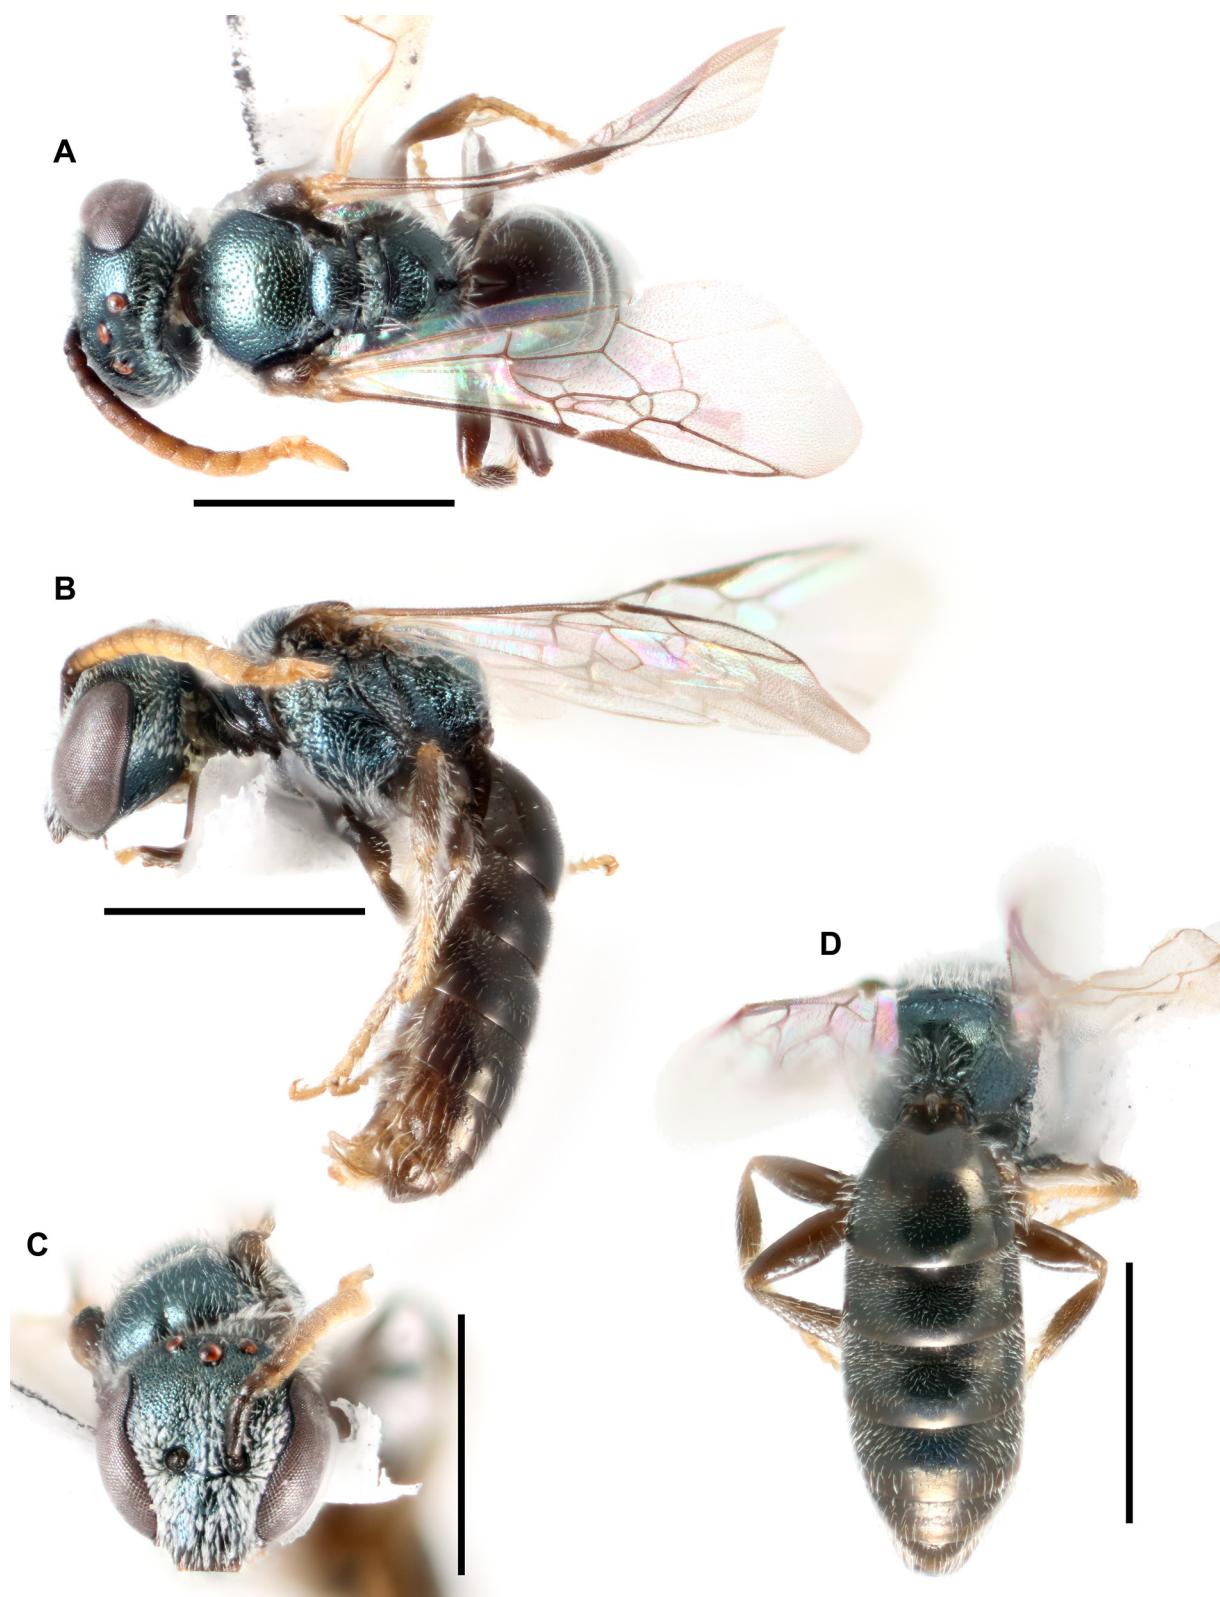

Fig. 46. *Lasioglossum (D.) perparvum* (Ellis, 1914), ♂ (ASUHIC). **A.** Dorsal habitus. **B.** Lateral habitus. **C.** Face. **D.** Metasoma and propodeum. Scale bars = 1 mm.

shiny (dull and tessellate in *L. perparvum*). Males have the face covered in dense tomentum up to upper ocular tangent (dense tomentum limited to paraocular area in *L. perparvum*).

Etymology

Ellis (1914) formed the specific epithet ‘*perparvus*’ from the Latin prefix ‘*per-*’ (very) and the adjective ‘*parvus*’ (little).

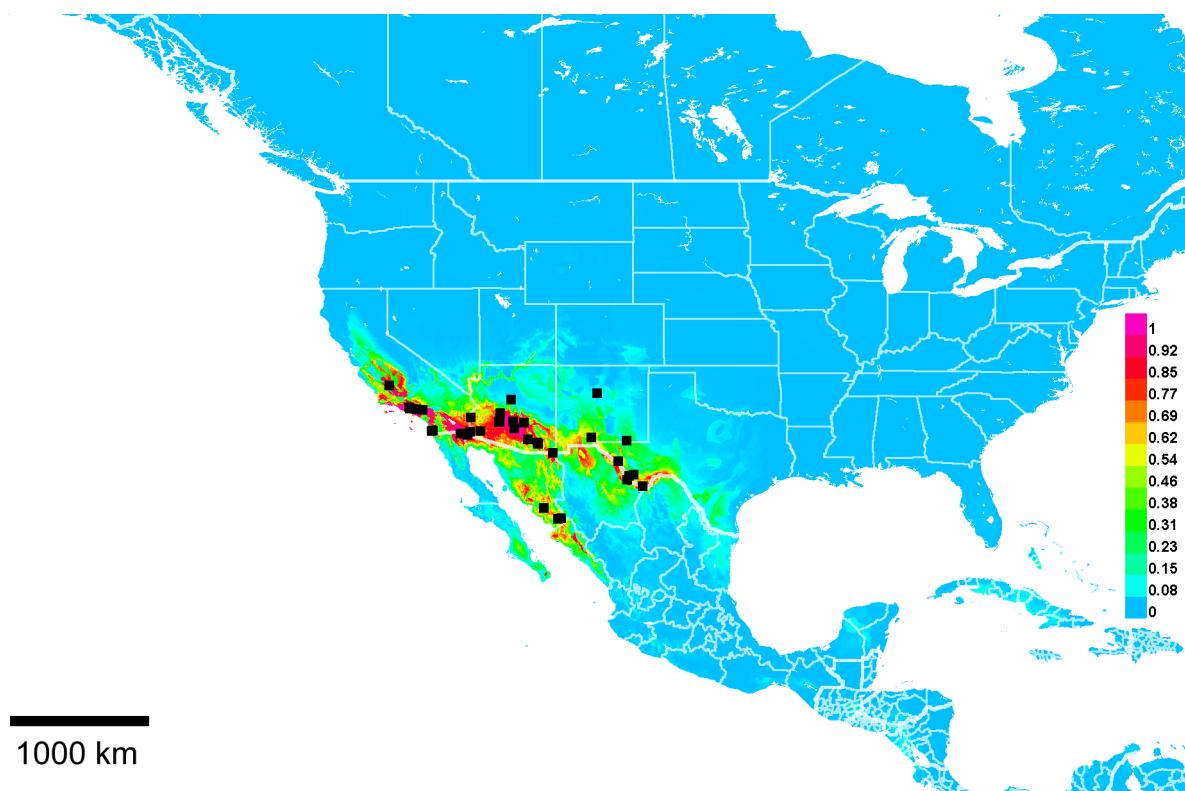

Fig. 47. Georeferenced collection records of *Lasioglossum (D.) perparvum* (Ellis, 1914) (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

Range

California and Sonoran and Chihuahuan Deserts (Fig. 47).

Floral hosts

ASTERACEAE: *Helianthus*: *H. annuus* • *Pluchea*: *P. sericea* (Nutt.) Coville • BORAGINACEAE: *Heliotropium* • BRASSICACEAE: *Nasturtium* W.T.Aiton: *N. officinale* R.Br. • *Physaria*: *P. gordonii* • CONVOLVULACEAE: *Convolvulus* L.: *C. arvensis* L. • EUPHORBIACEAE: *Euphorbia* • FABACEAE: *Medicago*: *M. sativa* • *Parkinsonia* • LAMIACEAE: *Mentha*: *M. spicata* • MALVACEAE: *Gossypium* • MYRTACEAE Juss.: *Melaleuca* L. • POLYGONACEAE: *Antigonon* Endl. • RHAMNACEAE: *Condalia* • SOLANACEAE: *Physalis*: *P. acutifolia* • TAMARICACEAE: *Tamarix*: *T. ramosissima*.

Some additional floral hosts were reported in Moure & Hurd (1987), but many of these are likely attributable to *L. deludens* sp. nov.

DNA barcodes

Nine confirmed sequences available (BOLD process IDs: NCBEE350-21, NCBEE361-21, NCBEE367-21, NCBEE370-21, NCBEE371-21, NCBEE373-21, NCBEE374-21, NCBEE375-21, NCBEE464-21). These sequences are identical (0% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. holzenthali* sp. nov. in the Nearctic (2.91% minimum interspecific p-distance) and an undescribed species in the Neotropics (1.65% minimum interspecific p-distance). Five fixed nucleotide substitutions distinguish *L. perparvum* from all other Nearctic species of the *L. gemmatum* complex: 132(A), 249(C), 334(G), 358(A), and 360(T) ([Supp. file 2](#)).

Comments

Uncommon. Most specimens determined as *L. perparvum* in various collections prior to this work were the much more common *L. deludens* sp. nov. Morphological examination and DNA barcodes suggest that *L. perparvum* may belong to a large and difficult species complex with most of its diversity in the Neotropics.

LasioGLOSSUM (Dialictus) profundum sp. nov.

[urn:lsid:zoobank.org:act:733EE382-5F27-440B-A179-DE2D0A166E65](https://doi.org/10.1545/zoobank.733EE382-5F27-440B-A179-DE2D0A166E65)

Figs 48–50, 76L, 81A, 82A

Diagnosis

Females of *L. profundum* sp. nov. have the tegula very small (maximum length <45% ITS and barely reaching posterior margin of mesoscutum in dorsal view if at all), dark brown, with inner posterior margin straight, and impunctate except on far anterior margin; mesoscutum coarsely punctate (punctures as large as on mesepisternum, but sparser medially (IS = 1–2 PD)); mesoscutum and mesepisternum usually dull, tessellate to imbricate (mesoscutum sometimes shiny posteriorly); metapostnotum shiny with strong, coarse rugae; T1–T3 apical rims finely punctate; T2–T3 with tomentum covering half or more length of segment laterally; and mesoscutum with dense erect pubescence (each seta less than its length from the one nearest it and no gaps more than 0.5 OD wide visible in lateral view) and short intervening setae 0.25 OD long or more.

Females of *L. profundum* sp. nov. are most similar to those of *L. deludens* sp. nov. and *L. rufodeludens* sp. nov. See the diagnosis for *L. deludens* for a comparative diagnosis between these three species. They are also somewhat similar to those of *L. holzenthali* sp. nov. and *L. perparvum*, both of which have the tegula with at least some fine punctures medially and T2–T3 with tomentum covering less than half length

of segment laterally. In addition, females of *L. holzenthalii* have the T1–T3 apical rims with larger and deeper punctures. Females of *L. perparvum* have the mesoscutum with sparse erect pubescence (each seta about its length from the one nearest it and some gaps more than 0.5 OD wide visible in lateral view) and very short intervening setae no more than stubble, mesoscutum more finely punctate, and metapostnotum dull with fine rugae.

Males of *L. profundum* sp. nov. have the tegula relatively small (maximum length less than half ITS and not reaching posterior margin of mesoscutum in dorsal view), dark brown, with inner posterior margin weakly concave and a blunt posterior angle, and impunctate except on far anterior margin and sometimes a few punctures on posterior margin; mesoscutum shiny and usually coarsely, moderately densely punctate (IS = 1–2 PD); metapostnotum usually shiny with strong subparallel rugae; face with dense tomentum up to eye emargination and slightly above; mesoscutum with dense erect pubescence (no gaps more than 0.5 OD visible in lateral view); and head and mesosoma usually deep blue.

Males of *L. profundum* sp. nov. are most similar to those of *L. deludens* sp. nov. and *L. rufodeludens* sp. nov. See the diagnosis for *L. deludens* for a comparative diagnosis between these three species. They are also somewhat similar to those of *L. holzenthalii* sp. nov. and *L. perparvum*, both of which have the face with dense tomentum limited to paraocular area and tegula usually punctate medially (rarely may be impunctate in *L. holzenthalii*). In addition, males of *L. holzenthalii* have the T1–T3 apical rims deeply and distinctly punctate. Males of *L. perparvum* have the mesoscutum with sparse erect pubescence (some gaps more than 0.5 OD visible in lateral view) and metapostnotum dull with fine rugae.

Etymology

The specific epithet ‘*profundum*’ is a Latin adjective meaning ‘deep’ or ‘profound’. It is a reference to this species’ deep blue and brown colouration, deep punctures, and its abundance near the deep caves at Carlsbad Caverns National Park. An appropriate translation would be the deep sweat bee.

Description

Female

COLOURATION. Head and mesosoma blue to blue-green; clypeus apex black; labrum black; mandible orange with black base and red apex; flagellum dark reddish brown dorsally, light brown ventrally. Pronotal lobe black; legs reddish brown; tegula dark brown; wing membrane hyaline, veins with subcosta dark brown, otherwise brown to light brown. Metasoma black with rims of terga and sterna narrowly translucent yellow.

PUBESCENCE. Body pile colour white. Tomentum dense on paraocular area, gena anteriorly, pronotal collar and lobe, space between pronotal lobe and tegula, and T2–T3 basolaterally; sparse on T4 throughout. Mesoscutum pubescence thin to moderately plumose. Wing setae dark, short and dense. Acarinarial fan complete, dense. T2 fringes sparse, T3 fringes sparse.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense in basal third ($IS < 1$ PD), large and irregularly spaced apically ($IS < 2$ PD); supraclypeal area shiny, with punctures dense ($IS \leq 1$ PD); paraocular area imbricate around antenna socket, otherwise shiny, with punctures crowded ($IS = 0$ PD), slightly sparser around antenna socket ($IS \leq 1$ PD); frons shiny, with punctures crowded ($IS = 0$ PD); vertex shiny, with punctures dense laterally ($IS < 1$ PD), sparse medially ($IS = 1–3$ PD); gena shiny, with punctures dense ($IS < 1.5$ PD); postgena shiny, becoming imbricate posteriorly. Tegula punctures absent; mesoscutum tessellate, with punctures dense ($IS < 1$ PD), becoming moderately sparse submedially and anteromedially ($IS = 1–2$ PD); scutellum tessellate, with punctures dense marginally and on median line ($IS < 1$ PD), moderately sparse submedially ($IS = 1–2$ PD); metapostnotum weakly imbricate, becoming tessellate posteriorly, with rugae strong, anastomosing, reaching posterior margin; preepisternum imbricate with crowded punctures ($IS = 0$ PD); hypoepimeron imbricate, with punctures dense ($IS < 1$ PD); mesepisternum imbricate, with punctures dense ($IS \leq 1$ PD), becoming crowded medially ($IS = 0$ PD); metepisternum finely ruguloso-lineate dorsally, ruguloso-punctate ventrally; propodeum lateral surface tessellate, posterior surface tessellate. T1 anterior slope coriarious, disc weakly coriarious, with punctures moderately dense ($IS = 1–2$ PD), minute and sparse on rim laterally ($IS = 1–4$ PD), absent in large subapical lateral boss and on rim medially; T2 disc shiny, with punctures moderately dense ($IS = 1–2$ PD), apical rim weakly coriarious, with punctures minute, sparse ($IS = 1–4$ PD).

STRUCTURE. Face length/width ratio 0.82 (± 0.01 SD); clypeus apicolateral denticles low rounded knobs; gena/eye width ratio 0.86 (± 0.13 SD). Pronotal angle slightly obtuse, nearly right-angled; intertegular span

0.91 (± 0.05 SD) mm; mesoscutum length/width ratio 0.85 (± 0.03 SD); mesoscutum/scutellum length ratio 2.82 (± 0.11 SD); scutellum/metanotum length ratio 1.68 (± 0.15 SD); metanotum/metapostnotum length ratio 0.8 (± 0.06 SD); forewing with 3 submarginal cells; tegula enlarged, nearly reaching posterior margin of mesoscutum; inner margin straight; tegula length 0.36 (± 0.02 SD) mm, width 0.21 (± 0.01 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina strong, straight. T2 depressed apical rim less than 50% of tergum. (n = 10)

VARIATION. The labrum and flagellum ventral surface can vary from black to orange, the mesoscutum posterior half can vary from strongly tessellate to shiny, and the T1 anterior slope can vary from coriarious to shiny.

Male

COLOURATION. Head and mesosoma blue to blue-green; clypeus apex black; labrum black; mandible orange with black base and red apex; flagellum dark reddish brown dorsally, orange ventrally. Pronotal lobe black; legs black to dark reddish brown; tegula dark brown; wing membrane hyaline, veins with subcosta dark brown, otherwise brown to light brown. Metasoma black with depressed apical rims of terga and sterna and downcurved lateral areas of terga broadly translucent reddish brown.

PUBESCENCE. Body pile colour white. Tomentum moderately dense on face below eye emargination, gena, pronotal angle and lobe, and space between pronotal lobe and tegula; sparse on preepisternum and metepisternum. Mesoscutum pubescence simple to moderately plumose. Wing setae dark and light intermixed, short and dense. Sterna pubescence short (0.5–1.5 OD), moderately plumose, sparse.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense (IS < 1 PD); supraclypeal area shiny, with punctures dense (IS \leq 1 PD); paraocular area shiny, with punctures crowded (IS = 0 PD); frons reticulate, with punctures crowded (IS = 0 PD); vertex shiny, with punctures dense laterally (IS < 1 PD), moderately dense medially (IS = 1–2 PD); gena shiny, with punctures fine, dense (IS \leq 1 PD), obscure; postgena shiny to weakly imbricate-lineate. Tegula punctures absent; mesoscutum shiny, becoming weakly tessellate anteromedially, with punctures moderately dense (IS = 1–2 PD), becoming dense on lateral and posterior margins (IS < 1 PD); scutellum shiny, with punctures dense (IS < 1 PD); metanotum shiny and densely punctate (IS < 1 PD); metapostnotum shiny to tessellate, with rugae strong, subparallel, nearly reaching posterior margin; preepisternum areolate; hypoepimeron areolate, with punctures crowded (IS = 0 PD); mesepisternum shiny, with punctures crowded (IS = 0 PD); metepisternum areolate, becoming smooth dorsally; propodeum lateral surface shiny, with punctures crowded (IS = 0 PD), posterior surface shiny and moderately densely punctate (IS = 1–2 PD), becoming crowded laterally (IS = 0 PD). T1 anterior slope shiny, disc shiny, with punctures dense (IS \leq 1.5 PD), becoming sparse in small subapicolateral boss (IS = 1–4 PD) and absent on rim medially; T2 disc shiny, with punctures dense (IS \leq 1 PD), apical rim shiny, with punctures absent.

STRUCTURE. Face length/width ratio 0.86 (± 0.01 SD); gena/eye width ratio 0.74 (± 0.07 SD). Pronotal angle obtuse; intertegular span 0.8 (± 0.11 SD) mm; mesoscutum length/width ratio 0.89 (± 0.03 SD); mesoscutum/scutellum length ratio 2.82 (± 0.08 SD); scutellum/metanotum length ratio 1.85 (± 0.15 SD); metanotum/metapostnotum length ratio 0.73 (± 0.08 SD); forewing with 3 submarginal cells; tegula enlarged, nearly reaching posterior margin of mesoscutum in dorsal view; inner posterior margin weakly concave; tegula length 0.36 (± 0.05 SD) mm, width 0.2 (± 0.03 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina absent. (n = 10)

GENITALIA. As in Fig. 76L. Gonocoxite about 1.8 times as broad as gonostylus. Gonostylus boot-shaped, strongly concave on outer margin and sharply angled at inner basal margin, with sparse long setae dorsally and short setae apically and along inner margin. Penis valves convergent apically, widely separated basally, with sparse short setae laterally. Retorse lobe truncate apically, about 2.5 times as long as broad.

VARIATION. The mesoscutum punctures can vary from large and dense ($IS < 1$ PD) to fine and sparse ($IS = 1–3$ PD), the metapostnotal rugae can vary from parallel to anastomosing, the propodeum lateral face can vary from distinctly punctate to almost rugulose, and the apical rims of T1–T3 can be entirely impunctate or with a few moderately sparse punctures near the premarginal line ($IS = 1–2$ PD).

Range

Chihuahuan Desert (Fig. 50).

Floral hosts

ANACARDIACEAE: *Rhus* • BORAGINACEAE: *Nama* • BRASSICACEAE: *Lepidium*: *L. integrifolium* • *Physaria*: *P. argyraea* (A.Gray) O’Kane & Al-Shehbaz • FABACEAE: *Acacia*: *A. greggii* • *Dalea* L.: *D. radicans* S.Watson • ROSACEAE: *Fallugia* Endl.: *F. paradoxa* (D.Don) Endl. ex Torr. • SOLANACEAE: *Chamaesaracha*: *C. crenata* Rydb. • *Solanum*.

DNA barcodes

Five confirmed sequences available (BOLD process IDs: DLII048-06, DLII1120-07, DLII1699-09, DLIII115-18, LASNA048-08). There is a small amount of divergence within these sequences (0.16% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. tegulare* (0.76% minimum interspecific p-distance). No fixed nucleotide substitutions distinguish *L. profundum* sp. nov. from all other species of the *L. gemmatum* complex, but one fixed nucleotide substitution distinguishes it from the closely related *L. puteulanum* and *L. tegulare*: 390(T) (Supp. file 2).

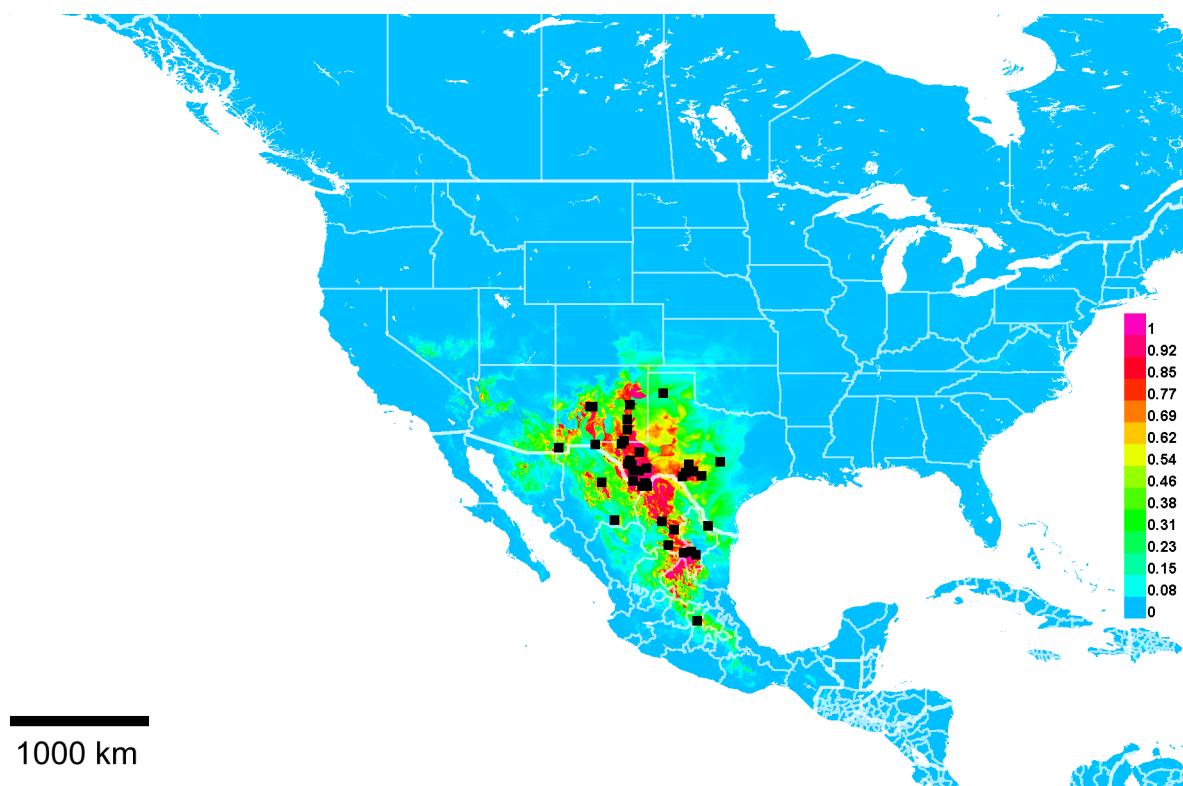

Fig. 50. Georeferenced collection records of *Lasioglossum (D.) profundum* sp. nov. (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

Lasioglossum (Dialictus) pseudotegulare (Cockerell, 1896)

Halictus pseudotegularis Cockerell, 1896: 294 (holotype, ♀, deposited in USNM, examined).

Halictus pseudotegularis – Cockerell 1899: 5 (catalogue).

Halictus (Chloralictus) pseudotegularis – Sandhouse 1924: 2, 8 (key to species), 11 (comparison to *ellisiae*). — Ellis 1914: 101 (comparison to *jamaicae* = *gemma*).

Lasioglossum (Chloralictus) pseudotegulare – Michener 1951: 1117 (catalogue).

Dialictus pseudotegularis – Hurd 1979: 1970 (catalogue). — Moure & Hurd 1987: 125 (catalogue).

Diagnosis

Females of *L. pseudotegulare* have the face relatively long (length/width ratio usually ≥ 0.83); tegula large (maximum length usually more than half ITS and reaching or exceeding posterior margin of mesoscutum in dorsal view), densely punctate (IS < 1 PD), and with inner posterior margin strongly concave and a rounded posterior projection 0.5–1 OD in size; metapostnotum finely reticulate with shallow subparallel rugae; mesepisternum shiny with at most weak microsculpture; mesoscutum with dense erect pubescence (each seta less than its length from the one nearest it and no gaps more than 0.5 OD visible in lateral view) and short intervening setae 0.25 OD long or more; disc of T4 with sparse tomentum; mesoscutum concolourous with propodeum; apical rims of T1–T2 sometimes distinctly punctate (especially in Sonoran Desert specimens), and gena narrower than eye in lateral view.

Females of *L. pseudotegulare* are most similar to those of *L. angelicum* sp. nov., *L. gaudiale*, and *L. magnitegula* sp. nov. Females of *L. angelicum* have the metapostnotum shiny with strong anastomosing rugae and face slightly shorter (length/width ratio ≤ 0.83). Females of *L. gaudiale* have the gena about as wide as eye in lateral view, metapostnotum usually shiny, and tegula with a posterior point narrower than 0.5 OD. Females of *L. magnitegula* have the mesoscutum with sparse erect pubescence (each seta about its length from the one nearest it) and very short intervening setae no more than stubble, T4 without tomentum, mesoscutum more greenish, golden, or reddish, contrasting with bluer propodeum, and apical rims of T1–T2 impunctate.

Males of *L. pseudotegulare* have the face relatively long (length/width ratio usually > 0.86); tegula large (as in the female); mesepisternum densely punctate (IS < 1 PD); metapostnotum tessellate to finely reticulate with shallow subparallel rugae; discs of T1–T2 deeply, distinctly, and densely punctate (IS ≤ 1 PD); T1–T2 apical rims with numerous deep, dense punctures basolaterally (IS ≤ 1 PD); and head and mesosoma uniformly coloured.

Males of *L. pseudotegulare* are most similar to those of *L. angelicum* sp. nov. and *L. magnitegula* sp. nov. Males of *L. angelicum* have the face shorter (length/width ratio ≤ 0.86) and discs of T1–T3 more sparsely punctate (IS = 1–2 PD). Males of *L. magnitegula* have the T1–T2 apical rims impunctate and mesoscutum with a more greenish or golden tint, contrasting with the bluer propodeum. In direct comparison, the mesosoma punctures are somewhat larger and coarser in *L. magnitegula* than in *L. pseudotegulare*.

A similar, undescribed species only known from Veracruz may be confused with *L. pseudotegulare*, but can be separated in both sexes by the metapostnotum shiny with strong rugae and tegula usually orange (dark brown in *L. pseudotegulare*).

Some other species in the *L. stictaspis* species complex can also be very similar in both sexes. Most have the mesepisternum dull or more sparsely punctate (IS = 1–2 PD), metapostnotum with strong anastomosing rugae, or T1–T2 less distinctly punctate, but a few can only be distinguished by a shorter face.

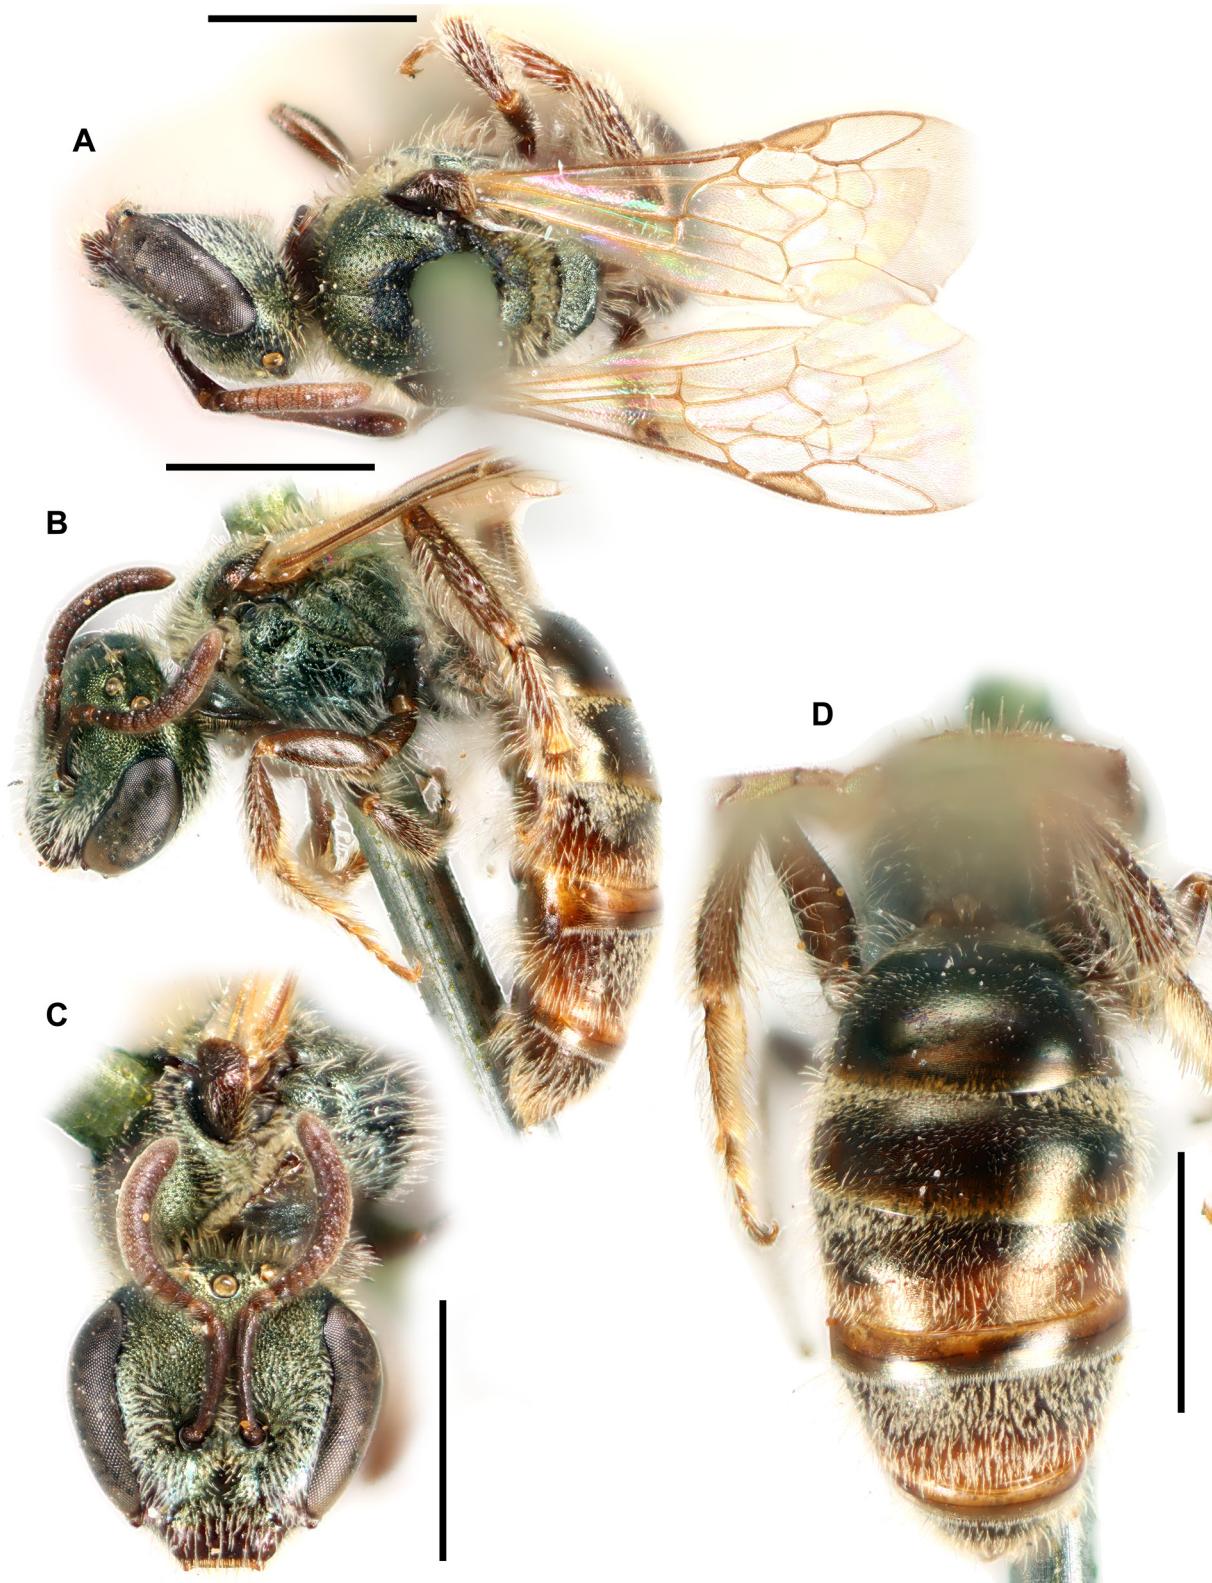

Fig. 51. *Lasioglossum (D.) pseudotegulare* (Cockerell, 1896), ♀, holotype (USNM 12065). **A.** Dorsal habitus. **B.** Lateral habitus. **C.** Face. **D.** Metasoma. Scale bars = 1 mm.

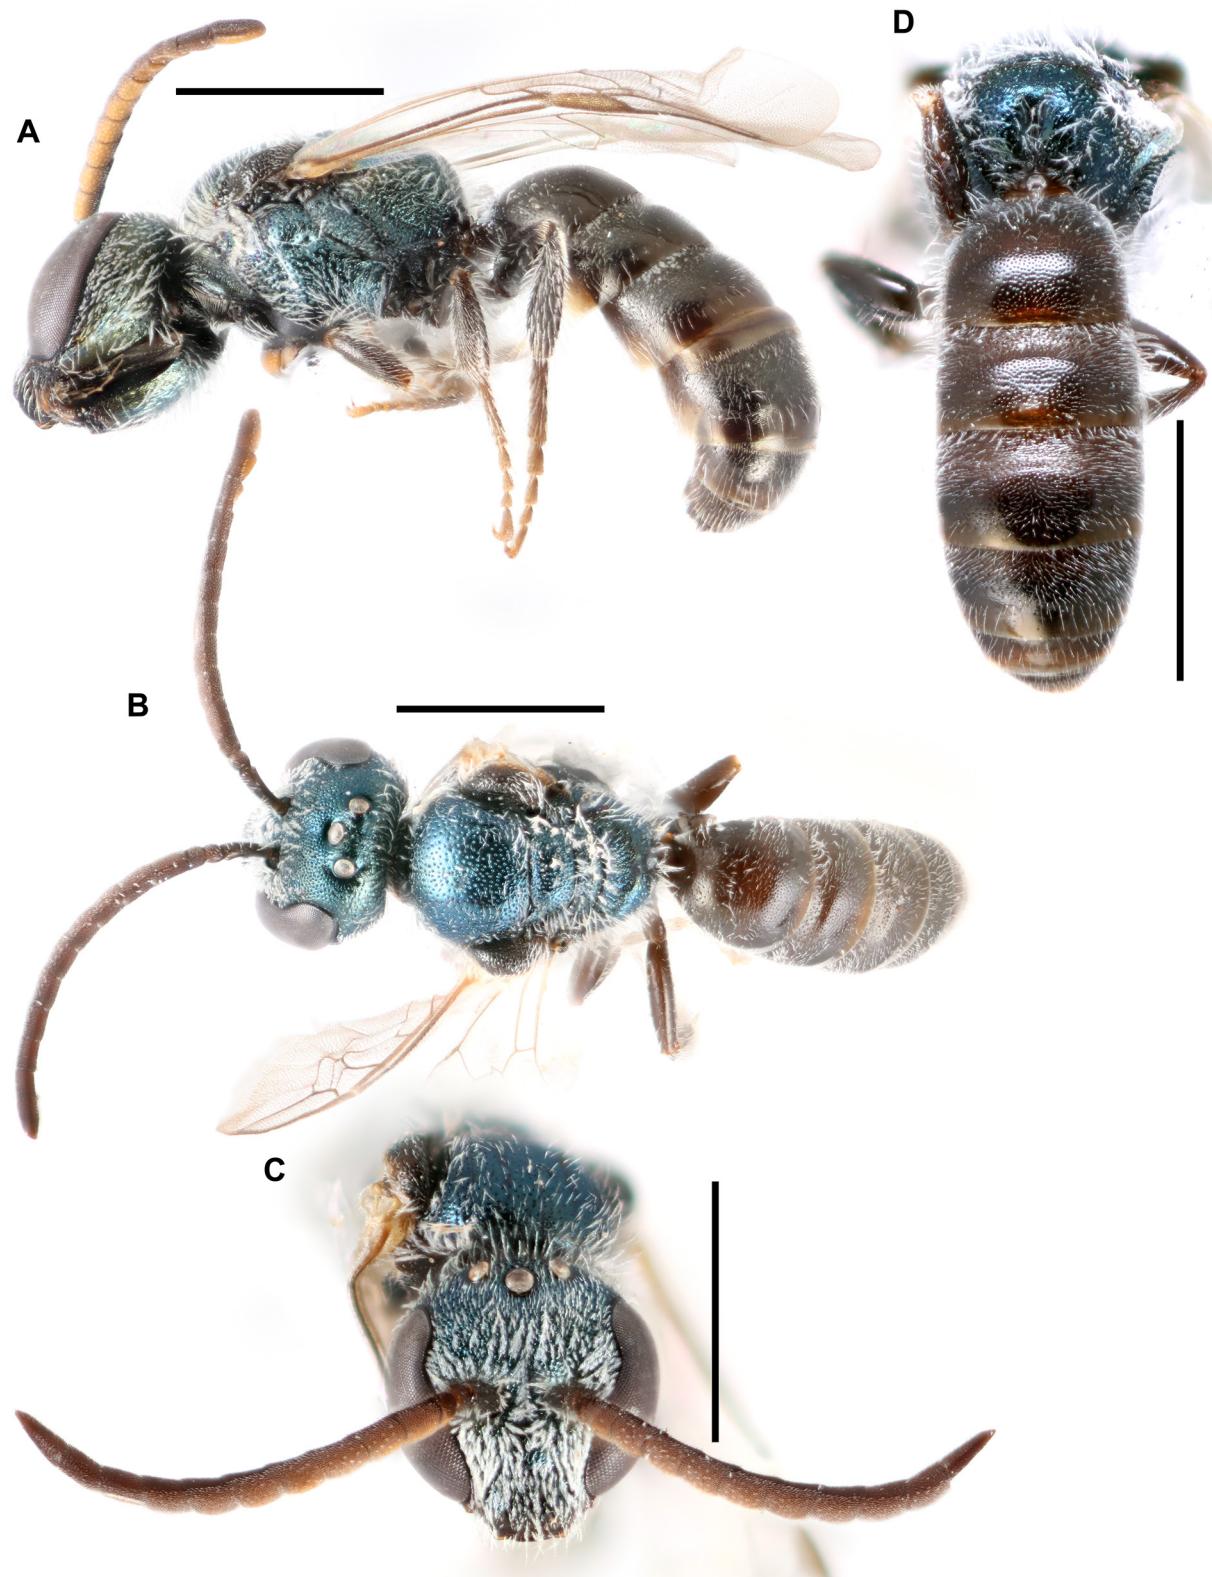

Fig. 52. *Lasioglossum (D.) pseudotegulare* (Cockerell, 1896), ♂ (A = ASUHIC0112600; B–C = ASUHIC0113605; D = ASUHIC0112865). A. Lateral habitus. B. Dorsal habitus. C. Face. D. Metasoma and propodeum. Scale bars = 1 mm.

Etymology

Cockerell (1896) formed the specific epithet ‘*pseudotegularis*’ from the Greek noun ‘*pseudos*’ (lie), the Latin noun ‘*tegula*’ (roof tile, literally ‘covering instrument’, now applied to the sclerite covering the wing base), and the Latin adjectival suffix ‘-aris’ (of or pertaining to).

Material examined

Range

Tropics of eastern and western Mexico, north to southern Arizona (Fig. 53).

Floral hosts

BRASSICACEAE: *Physaria*: *P. gordonii* • FABACEAE: *Medicago*: *M. sativa* • MALVACEAE: *Gossypium* • PAPAVERACEAE: *Argemone*: *A. mexicana* L.

DNA barcodes

Twenty-three confirmed sequences available (BOLD process IDs: BBLEG172-17, DLIII133-19, NCBEE340-21, NCBEE344-21, NCBEE345-21, NCBEE346-21, NCBEE351-21, NCBEE353-21, NCBEE354-21, NCBEE355-21, NCBEE356-21, NCBEE358-21, NCBEE359-21, NCBEE360-21, NCBEE362-21, NCBEE372-21, NCBEE376-21, NCBEE377-21, NCBEE378-21, NCBEE379-21, NCBEE380-21, NCBEE381-21, NCBEE382-21). There is a moderate amount of divergence within these sequences (0.79% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. carlinvillense* (1.07% minimum interspecific p-distance). One fixed nucleotide substitution distinguishes *L. pseudotegulare* from all other Nearctic species of the *L. gemmatum* complex: 255(T) ([Supp. file 2](#)).

Comments

Specimens from the Sonoran Desert usually have the apical rims of T1–T2 as distinctly punctate as the discs (except in the middle of the rim of T1), while Neotropical specimens usually have the apical rims of T1–T2 indistinctly punctate or impunctate. It is conceivable that the Sonoran and Neotropical populations are two different species. However, DNA barcodes do not distinguish specimens from Arizona, Jalisco, Puebla, or Chiapas, a few Sonoran specimens lack punctures on the rims of T1–T2 (and vice versa), and no other morphological differences between populations can be found. Currently, there is insufficient evidence to support a two-species hypothesis.

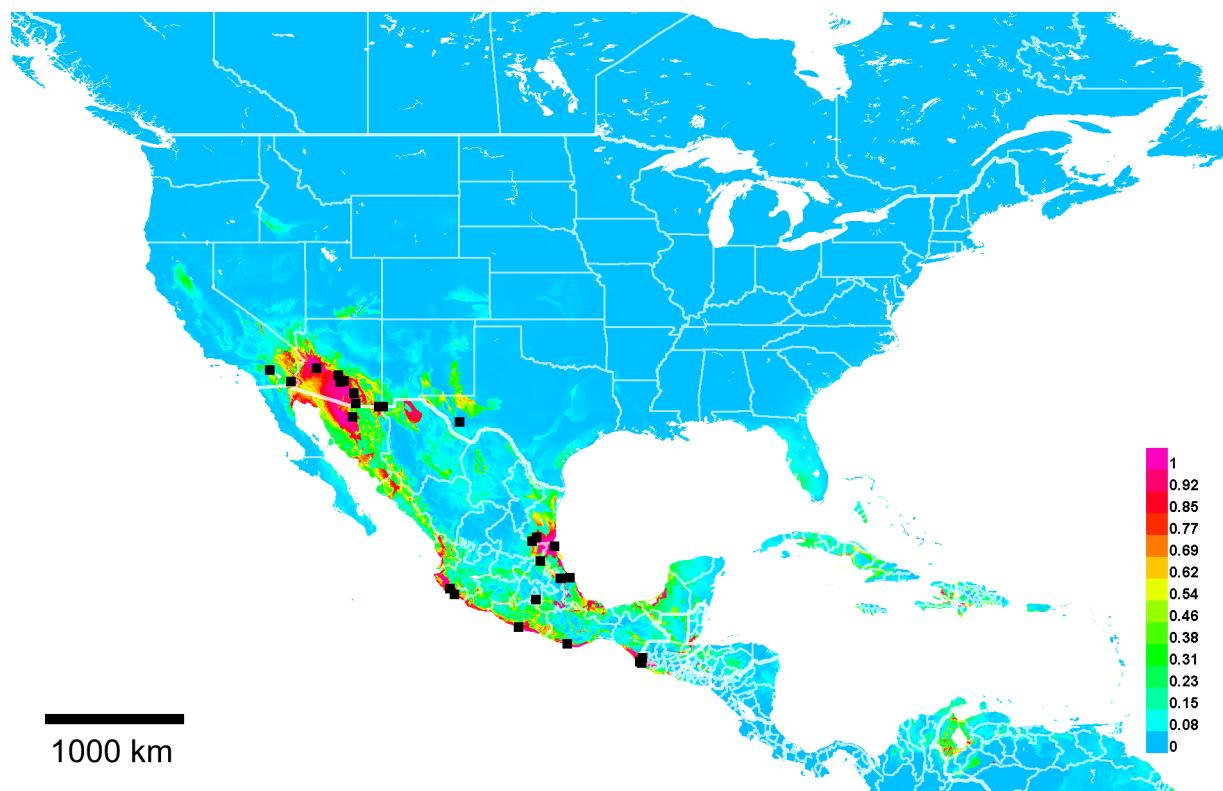

Fig. 53. Georeferenced collection records of *Lasioglossum (D.) pseudotegulare* (Cockerell, 1896) (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

The record of *L. pseudotegulare* in De Luca *et al.* (2019) was misidentified by J. Gardner and is in fact a *L. gaudiale*.

***Lasioglossum (Dialictus) puteulanum* Gibbs, 2009**

Figs 54–56, 92A, 101A, 118A

Lasioglossum (Dialictus) puteulanum Gibbs, 2009a: 25 (holotype, ♀, deposited in PCYU, examined).

Lasioglossum (Dialictus) puteulanum – Gibbs 2011: 25, 32 (key to species), 159 (review).

Diagnosis

Females of *L. puteulanum* have the tegula relatively small (reaching but not exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin weakly concave, and sparsely punctate (IS = 1–2 PD); face relatively long (length/width ratio usually >0.83); frons reticulate-punctate, without even narrow shiny interspaces between punctures; metapostnotum with coarse, anastomosing rugae, shiny in basal half; mesepisternum strongly imbricate to rugulose with crowded, indistinct punctures (IS = 0 PD); T3 with tomentum limited to basolateral patches; and head and mesosoma usually blue-green to deep blue.

Females of *L. puteulanum* are most similar to those of *L. helianthi*, *L. lepidii*, and *L. tegulare*, all of which have the face shorter (length/width ratio usually ≤0.83) and head and mesosoma usually blue-green to olive green. In addition, females of *L. helianthi* have the T3 disc with sparse tomentum throughout, *L. lepidii* have the frons and mesepisternum with very dense (IS <0.5 PD) but distinctly separated punctures, the frons appearing smooth and shiny, and *L. tegulare* have the tegula more densely punctate (IS ≤1 PD).

Males of *L. puteulanum* have the tegula relatively small (as in the female); mesoscutum relatively coarsely and moderately densely punctate (IS = 1–2 PD); metapostnotum shiny with strong subparallel rugae; disc of T2 uniformly densely punctate (IS ≤1 PD) including premarginal line; face with uniformly sparse tomentum below eye emargination; and head and mesosoma usually blue to blue-green.

Males of *L. puteulanum* are most similar to those of *L. ellisiae*, *L. helianthi*, *L. lepidii*, and *L. tegulare*. Males of *L. ellisiae* and *L. helianthi* have the mesoscutum usually more finely and densely punctate (IS ≤1 PD). Males of *L. ellisiae* and *L. lepidii* have the disc of T2 more finely and sparsely punctate in apical half (IS = 1–2 PD), not strongly contrasting with apical rims across the premarginal line. Males of *L. tegulare* have the tegula more densely punctate (IS ≤1 PD), face with sparser tomentum more limited to paraocular area, and head and mesosoma usually greener.

Etymology

The specific epithet ‘*puteulanum*’ is a medieval Latin adjective meaning ‘blue’.

Range

Southeastern United States and Hawaii (Fig. 56).

Floral hosts

ASTERACEAE: *Bidens*: *B. pilosa* L.

DNA barcodes

Twenty confirmed sequences available (BOLD process IDs: BWTWO856-10, DIAL027-06, DIAL028-06, DIAL029-06, DIAL487-06, DIAL496-06, DIAL498-06, DIAL501-06, DIAL513-06, DIAL514-06, DIAL866-06, DLII393-07, DLII396-07, DLII398-07, DLII411-07, DLII435-07, DLII465-07, DLII472-07, DLII474-07, DLIII113-18). There is a moderate amount of divergence within these sequences (0.94% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. tegulare* (0.31% minimum

interspecific p-distance). No fixed nucleotide substitutions distinguish *L. puteulanum* from all other species of the *L. gemmatum* complex, but two fixed nucleotide substitutions distinguish it from the closely related *L. profundum* sp. nov. and *L. tegulare*: 339(C) and 609(T) ([Supp. file 2](#)).

Comments

Lasioglossum puteulanum was previously only known from the southeastern United States. It was first reported from Hawaii by Tabor & Koch (2021), but has evidently existed there and gone undetected for some time previously. The specimens of *L. helianthi* from Magnacca *et al.* (2013) were examined and found to be a mixed series including some *L. puteulanum*, and a successful DNA barcode from one of these specimens confirmed the identification. How *L. puteulanum* could have been moved from the southeastern United States to Hawaii is not known. It seems to be a unique case, as the three other species of *L. (Dialictus)* introduced to Hawaii are all native to California.

The Alabama specimen recorded here is unusual in that it has only two branches on the metatibial spur, which is normally diagnostic for *L. carlinvillense*. Its identification was based on other characters and is somewhat tenuous.

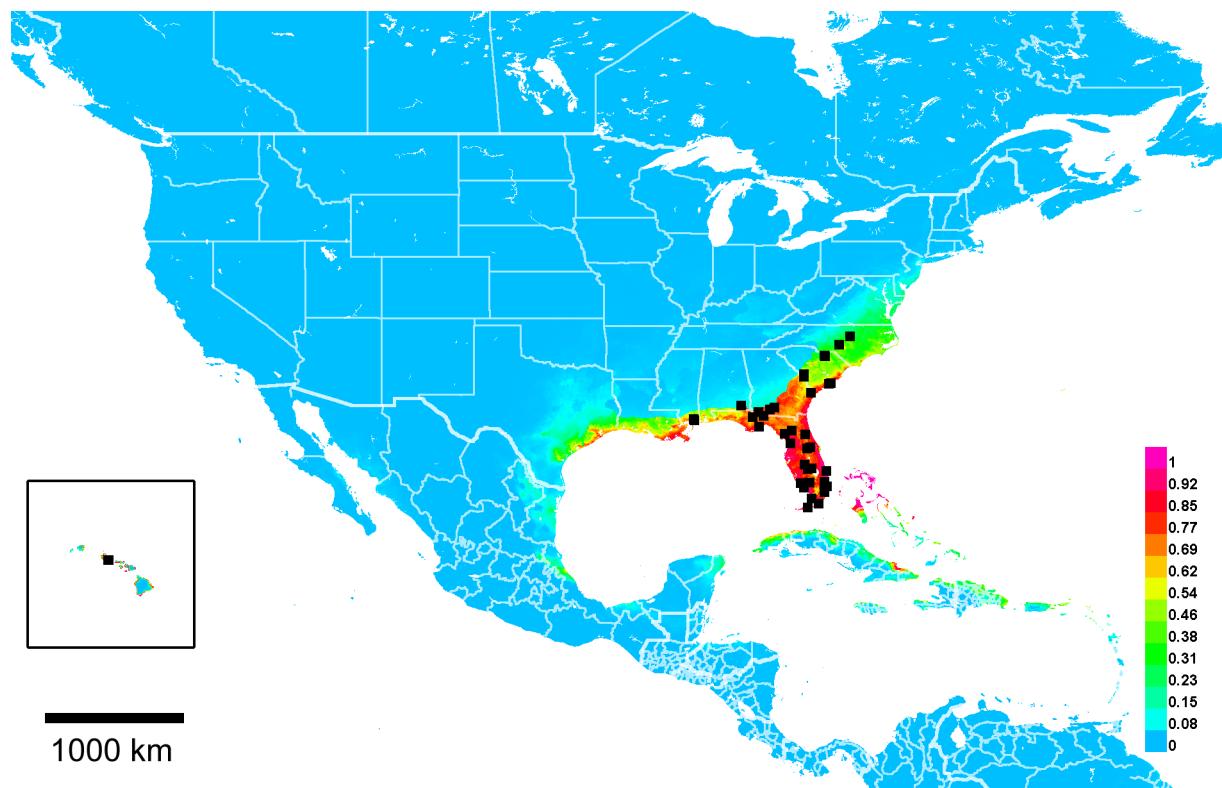

Fig. 56. Georeferenced collection records of *Lasioglossum (D.) puteulanum* Gibbs, 2009 (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence. Because many coastal records lacked soil data, the model was generated without soil type as an environmental variable.

***Lasioglossum (Dialictus) rufodeludens* sp. nov.**
[urn:lsid:zoobank.org:act:D04BB5BC-FD13-4140-8449-9CA4A9A6C241](https://doi.org/10.12695/EJT.2023.1000000000)
Figs 57–59, 76N

Diagnosis

Females of *L. rufodeludens* sp. nov. have the tegula relatively small (maximum length half or less ITS and barely reaching posterior margin of mesoscutum in dorsal view if at all), yellow-orange, impunctate, and with inner posterior margin straight; mesoscutum and mesepisternum completely dull, tessellate to imbricate; postgena smooth, shiny or lineolate; T1 anterior slope shiny (sometimes weakly coriarious but not appearing dull), and metasoma red-orange.

Females of *L. rufodeludens* sp. nov. are most similar to those of *L. deludens* sp. nov., *L. ellisiae*, and *L. profundum* sp. nov. Females of *L. ellisiae* have the tegula at least sparsely punctate and the inner posterior margin sinuous, mesoscutum and mesepisternum posterior half often shiny, postgena lineate, and T1 anterior slope dull and coriarious. See the diagnosis for *L. deludens* for a comparative diagnosis between the other similar species.

Males of *L. rufodeludens* sp. nov. have the tegula relatively small (as in the female); mesoscutum tessellate and moderately densely punctate (IS = 1–2 PD); and face with dense tomentum up to eye emargination. They are most similar to those of *L. deludens* sp. nov. and *L. profundum* sp. nov. See the diagnosis for *L. deludens* for a comparative diagnosis between these three species.

Both sexes are also somewhat similar to those of *L. gemmatum* and *L. surianae*, which have the tegula at least obscurely punctate and are restricted to the Caribbean islands and Florida keys. Females of these species also have the mesepisternum shiny, and males have the face with tomentum limited to lower paraocular area.

Etymology

The specific epithet ‘*rufodeludens*’ is a participle derived from the Latin adjective ‘*rufo*’ (red) plus the present participle ‘*deludens*’ (deceiving). It refers to this species’ red metasoma and its close similarity to *L. deludens* sp. nov. An appropriate translation would be the red deceiving sweat bee.

Description

Female

COLOURATION. Head and mesosoma blue to olive green; clypeus apex black; labrum reddish brown; mandible orange with black base and red apex; flagellum black dorsally, brown ventrally. Pronotal lobe reddish brown; legs reddish brown with femur-tibia joints and tarsi orange; tegula orange; wing membrane lightly infuscated, veins with subcosta dark brown, otherwise brown. Metasoma orange with dark spiracular spots on T3–T4 and rims of terga and sterna broadly translucent.

PUBESCENCE. Body pile colour white. Tomentum dense on gena, pronotal collar and lobe, and space between pronotal lobe and tegula; sparse on paraocular area, T2–T3 basolaterally, and T4 throughout. Mesoscutum pubescence thin to moderately plumose. Wing setae dark, short and dense. Acinarial fan complete, dense. T2 fringes sparse, T3 fringes sparse.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense in basal third ($IS \leq 1$ PD), large and irregularly sparse apically ($IS < 2$ PD); supraclypeal area shiny, with punctures moderately dense ($IS = 1$ – 2 PD); paraocular area imbricate around antenna socket, otherwise shiny, with punctures dense ($IS < 1$ PD), sparser around antenna socket ($IS \leq 1$ PD); frons shiny, with punctures fine, dense ($IS < 1$ PD); vertex shiny, with punctures dense laterally ($IS \leq 1$ PD), minute and sparse medially ($IS = 2$ – 4 PD); gena shiny, with punctures absent; postgena lineolate, becoming shiny anteriorly. Tegula punctures absent; mesoscutum tessellate, with punctures dense ($IS \leq 1$ PD), becoming sparser anteromedially ($IS = 1$ – 2 PD); scutellum tessellate, becoming shiny submedially, with punctures dense marginally ($IS < 1$ PD), moderately sparse submedially ($IS = 1$ – 2 PD); metapostnotum shiny, with rugae strong, anastomosing, reaching posterior margin; preepisternum areolate-rugulose; hypoepimeron weakly imbricate, with punctures dense ($IS < 1$ PD); mesepisternum imbricate, with punctures dense ($IS < 1$ PD); metepisternum weakly rugulose; propodeum lateral surface rugulose anteriorly, tessellate posteriorly, posterior surface tessellate. T1 anterior slope shiny, disc shiny, with punctures moderately sparse ($IS = 1$ – 2 PD), absent in large subapicalateral boss and on rim medially; T2 disc shiny, with punctures moderately dense ($IS = 1$ – 2 PD), apical rim weakly coriarious, with punctures minute, sparse ($IS = 2$ – 4 PD).

STRUCTURE. Face length/width ratio 0.81 (± 0.01 SD); clypeus apicolateral denticles low rounded knobs; gena/eye width ratio 0.89 (± 0.07 SD). Pronotal angle slightly obtuse, nearly right-angled; intertegular span 0.77 (± 0.05 SD) mm; mesoscutum length/width ratio 0.86 (± 0.03 SD); mesoscutum/scutellum length ratio 2.78 (± 0.25 SD); scutellum/metanotum length ratio 1.71 (± 0.18 SD); metanotum/metapostnotum length ratio 0.74 (± 0.08 SD); forewing with 3 submarginal cells; tegula enlarged, reaching posterior margin of mesoscutum; inner margin straight; tegula length 0.35 (± 0.02 SD) mm, width 0.2 (± 0.01 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina strong, straight. T2 depressed apical rim less than 50% of tergum. (n = 7)

VARIATION. The mesoscutum punctures can vary from moderately sparse ($IS = 1$ – 2 PD) to dense ($IS \leq 1$ PD) and the clypeus apical half, labrum, and pronotal lobe can vary from dark reddish brown to orange.

Male

COLOURATION. Head and mesosoma blue-green to olive green; clypeus apex black; labrum orange; mandible orange with black basal spot and red apex; flagellum reddish brown dorsally, orange ventrally. Pronotal lobe orange; legs reddish brown; tegula orange; wing membrane lightly infuscated, veins dark brown. Metasoma black with depressed apical rims and downcurved lateral areas of terga broadly translucent reddish brown.

PUBESCENCE. Body pile colour white. Tomentum dense on face below eye emargination, gena, pronotal angle and lobe, and space between pronotal lobe and tegula; sparse on metepisternum. Mesoscutum pubescence simple to moderately plumose. Wing setae dark, short and dense. Sterna pubescence short (< 1 OD), moderately plumose, sparse.

SURFACE SCULPTURE. Clypeus shiny, with punctures dense (IS < 1 PD); supraclypeal area shiny, with punctures dense (IS ≤ 1 PD); paraocular area shiny, with punctures fine, crowded (IS = 0 PD); frons shiny, with punctures fine, crowded (IS = 0 PD); vertex shiny, with punctures dense (IS < 1 PD); gena shiny, with punctures fine, dense (IS ≤ 1 PD); postgena imbricate-lineate. Tegula punctures absent; mesoscutum tessellate, becoming shiny posterolaterally, with punctures dense (IS ≤ 1 PD), becoming slightly sparser submedially (IS = 1–2 PD); scutellum shiny, with punctures dense (IS ≤ 1 PD); metanotum finely rugulose; metapostnotum shiny to imbricate, with rugae shallow, subparallel, nearly reaching posterior margin; preepisternum shiny with crowded punctures (IS = 0 PD); hypoepimeron shiny, with punctures crowded (IS = 0 PD); mesepisternum shiny, with punctures crowded (IS = 0 PD); metepisternum areolate, becoming smooth dorsally; propodeum lateral surface shiny to imbricate, with punctures dense (IS ≤ 1 PD), posterior surface shiny and densely punctate (IS ≤ 1 PD). T1 anterior slope shiny, disc shiny, with punctures fine, moderately dense (IS = 1–2 PD), becoming sparse in small subapicolateral boss (IS = 1–4 PD) and absent on rim; T2 disc shiny, with punctures moderately dense (IS = 1–2 PD), apical rim shiny, with punctures absent.

STRUCTURE. Face length/width ratio 0.86 (± 0.02 SD); gena/eye width ratio 0.66 (± 0.09 SD). Pronotal angle obtuse; intertegular span 0.7 (± 0.03 SD) mm; mesoscutum length/width ratio 0.91 (± 0.02 SD); mesoscutum/scutellum length ratio 2.84 (± 0.19 SD); scutellum/metanotum length ratio 1.84 (± 0.17 SD);

Fig. 59. Georeferenced collection records of *Lasioglossum* (D.) *rufodeludens* sp. nov. (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

metanotum/metapostnotum length ratio 0.68 (± 0.1 SD); forewing with 3 submarginal cells; tegula enlarged, nearly reaching posterior margin of mesoscutum in dorsal view; inner posterior margin straight; tegula length 0.34 (± 0.01 SD) mm, width 0.19 (± 0 SD) mm; propodeum lateral carinae not reaching dorsal margin; oblique carina absent. (n = 5)

GENITALIA. As in Fig. 76N. Gonocoxite about 1.7 times as broad as gonostylus. Gonostylus rounded on outer margin with no concavities, sinuous on inner margin, with sparse long setae in middle of inner margin and short setae apically. Penis valves divergent apically. Retorse lobe rounded, about 2.5 times as long as broad, evenly covered in short sparse setae.

VARIATION. The mesoscutum can vary from entirely tessellate to partially shiny posterolaterally and the metapostnotum can vary from mostly shiny to mostly imbricate.

Range

Tamaulipas, Nuevo Leon, and southern Texas (Fig. 59).

Floral hosts

FABACEAE: *Prosopis*: *P. laevigata* (Willd.) M.C.Johnst. • SALICACEAE: *Salix*: *S. nigra* • VERBENACEAE: *Lippia* L.

DNA barcodes

One confirmed sequence available (BOLD process ID: BOWGF941-09). It is most similar in terms of p-distance to *L. deludens* sp. nov. (1.59% minimum interspecific p-distance). Four fixed nucleotide substitutions distinguish *L. rufodeludens* sp. nov. from all other Nearctic species of the *L. gemmatum* complex: 102(C), 196(C), 537(G), and 630(T) ([Supp. file 2](#)).

There are five very similar sequences from Estación Biología de Chamela, Jalisco, which are not believed to be conspecific. In addition to the extreme geographic separation, one of the Jalisco specimens was photographed and it has a dark brown, punctate tegula.

Comments

Rare. The scarcity of specimens may be due in part to a lack of collecting effort in far southern Texas and northeastern Mexico, where *L. rufodeludens* sp. nov. is evidently restricted.

Lasioglossum (Dialictus) stictaspis (Sandhouse, 1923)
Figs 60–66, 76O, 81C, 89B, 91A, 100B, 111B, 112B, 114B

Dialictus stictaspis Sandhouse, 1923: 195 (holotype, ♂, deposited in USNM, examined).

Halictus (Chloralictus) albuquerquensis Michener, 1937: 316 (holotype, ♀, deposited in CAS, examined).

Lasioglossum (Dialictus) stictaspis – Michener 1951: 1119 (catalogue).

Lasioglossum (Chloralictus) albuquerquense – Michener 1951: 1112 (catalogue).

Dialictus stictaspis – Hurd 1979: 1971 (catalogue). — Moure & Hurd 1987: 131 (catalogue).

Dialictus albuquerquensis – Hurd 1979: 1964 (catalogue). — Moure & Hurd 1987: 89 (catalogue).

Diagnosis

See the diagnosis for the *L. stictaspis* species complex and the diagnosis for *L. paululum*. Females of *L. stictaspis* s. str., described from New Mexico, have the tegula relatively large (reaching and sometimes slightly exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin weakly

concave, and densely punctate ($IS \leq 1$ PD); metapostnotum dull, tessellate to finely reticulate, and usually with fine subparallel rugae; mesepisternum shiny (sometimes with weak microsculpture) and densely punctate ($IS < 1$ PD); mesoscutum dull and coarsely punctate (2–3 punctures between posterior end of parapsidal line and/or lateral edge of mesoscutum and some $IS = 1–2$ PD between parapsidal lines); T1–T2 discs finely and moderately sparsely punctate ($IS = 1–3$ PD) and apical rims impunctate; T3 with dense subapical band of tomentum (often medially interrupted); face short (length/width ratio ≤ 0.83) and gena narrower than eye in lateral view.

Females of *L. stictaspis* s. str. are most similar to those of *L. angelicum* sp. nov., *L. diabolicum* sp. nov., *L. ellisiae*, *L. gaudiale*, and *L. pseudotegulare*. Females of *L. angelicum* and *L. pseudotegulare* have the T1–T2 discs more deeply and densely punctate ($IS = 1–2$ PD) with some punctures often extending onto apical rims. In addition, females of *L. angelicum* have the metapostnotum shiny with strong anastomosing rugae, and females of *L. pseudotegulare* have the face slightly longer (length/width ratio usually > 0.83). Females of *L. ellisiae* have the tegula slightly smaller (not exceeding posterior margin of mesoscutum in dorsal view) and usually more sparsely punctate (up to $IS = 1–3$ PD), metapostnotum with strong, coarse rugae and basal half shiny, and T3 usually without subapical tomentum (rarely with a sparse, broadly interrupted band). Females of *L. gaudiale* have the metapostnotum with strong, coarse rugae and basal half shiny, gena about as wide as eye in lateral view, and T3 without subapical tomentum.

Males of *L. stictaspis* s. str. have the tegula densely punctate ($IS \leq 1$ PD), relatively large (slightly exceeding posterior margin of mesoscutum in dorsal view), and inner posterior margin concave, with a small rounded posterior projection about 0.5 lateral OD in size; metapostnotum tessellate to finely reticulate with shallow subparallel rugae; mesepisternum densely punctate ($IS < 1$ PD); mesoscutum coarsely and moderately densely punctate ($IS = 1–2$ PD); disc of T2 with punctures deep, distinct, and usually dense ($IS \leq 1$ PD); and T1–T2 apical rims impunctate.

Males of *L. stictaspis* s. str. are most similar to those of *L. angelicum* sp. nov., *L. diabolicum* sp. nov., *L. ellisiae*, and *L. pseudotegulare*. Males of *L. angelicum* and *L. pseudotegulare* have the T1–T2 apical rims punctate; in addition, males of *L. pseudotegulare* have the T2 disc even more densely punctate medially ($IS < 1$ PD). Males of *L. diabolicum* and *L. ellisiae* have the tegula slightly smaller (not exceeding posterior margin of mesoscutum in dorsal view) with inner posterior margin straight or sinuous and a blunt posterior angle or point narrower than 0.5 lateral OD, and usually more sparsely punctate in part ($IS \geq 1$ PD); in addition, males of *L. ellisiae* have the mesoscutum more uniformly and densely punctate ($IS \leq 1$ PD).

Lasioglossum stictaspis s. lat. is highly variable and a large number of specimens, especially those from south or west of New Mexico, may lack one or more of the above diagnostic characters, making them very difficult to separate from similar species.

Etymology

Sandhouse (1923) formed the specific epithet ‘*stictaspis*’ from the Greek adjective ‘*stiktos*’ (punctured, spotted) and the noun ‘*aspis*’ (shield). It likely refers to the punctured tegula of this species.

Range

Western Great Plains and Rio Grande River valley (*L. stictaspis* s. str.) and west to California, south throughout Mexico (*L. stictaspis* s. lat.).

DNA barcodes

Twenty-four confirmed sequences available, three haplotypes (BOLD process IDs: DLIII224-20, DLIII225-20, DLIII227-20 (haplotype 1); DLIII231-20, NCBEE336-21, NCBEE339-21, NCBEE343-21,

Fig. 66. *Lasioglossum (D.) stictaspis* (Sandhouse, 1923), ♂, Mexico morph (WRME). **A.** Lateral habitus. **B.** Dorsal habitus. **C.** Face. **D.** Metasoma and propodeum. Scale bars = 1 mm.

NCBEE347-21, NCBEE349-21, NCBEE357-21, NCBEE369-21, NCBEE404-21, NCBEE407-21, NCBEE412-21 (haplotype 2); DLIII124-18, DLIII128-19, DLIII129-19, DLIII130-19, DLIII131-19, DLIII132-19, DLIII135-19, DLIII136-19, NCBEE403-21, SMTPP733-15 (haplotype 3)). Haplotypes 2 and 3 are shared with *L. diabolicum* sp. nov. Haplotype 3 has some relatively deep divergence and may be possible to split into additional haplotypes. No fixed nucleotide substitutions distinguish all *L. stictaspis* from all other Nearctic species of the *L. gemmatum* complex, but one fixed substitution distinguishes haplotype 2: 402(G) ([Supp. file 2](#)).

Comments

The species treated by Gardner & Gibbs (2022) as *L. stictaspis* may include two species, the other one being *L. paululum*, described from Colorado. See that work for specimen records and range map. Specimens with a duller mesoscutum and ocellocular area, yellowish pubescence, and a slightly weaker T3 subapical band of tomentum match the holotype of *L. albuquerquense* and are here considered *L. stictaspis* s. str.. *Lasioglossum stictaspis* s. lat. ranges south throughout Mexico and west to California. It can have almost any combination of punctuation and surface sculpture in any location.

It is likely that *L. stictaspis* s. lat. comprises multiple species, but correlates between morphological, genetic, and geographic variation cannot be found to support a species hypothesis. One of these may be *L. paululum*, but additional species from Mexico, Arizona, or California are likely undescribed. More data is needed to clarify limits and relationships between these species.

Lasioglossum (Dialictus) surianae (Mitchell 1960)

Dialictus surianae – Hurd 1979: 1972 (catalogue). — Moure & Hurd 1987: 132 (catalogue).

Diagnosis

Females of *L. surianae* have the tegula very small (maximum length less than half ITS and not reaching posterior margin of mesoscutum in dorsal view) with inner posterior margin straight, translucent yellow, and very finely, sparsely punctate (IS = 2–6 PD); mesepisternum shiny and densely punctate (IS < 1 PD); postgena dull with lineolate microsculpture; frons shiny with distinct (but still very narrow) interspaces between punctures; and metasoma red-orange with terga reddish brown at base. The tegula punctures are so fine that at low magnification or at certain angles, they may not be visible and the tegula will appear impunctate.

Females of *L. surianae* are most similar to those of *L. deludens* sp. nov., *L. diabolicum* sp. nov., and *L. rufodeludens* sp. nov. Females of *L. deludens* and *L. rufodeludens* have the tegula impunctate except on extreme anterior margin and postgena smooth and shiny. In addition, females of *L. deludens* have the metasoma black to brown (sometimes slightly reddish on apical rims), and females of *L. rufodeludens* have the mesepisternum dull. Females of *L. diabolicum* have the frons dull and reticulate with no distinct interspaces between punctures.

Males of *L. surianae* have the tegula small (as in the female), face with tomentum limited to lower paraocular area, and mesepisternum shiny and densely punctate (IS ≤ 1 PD). The only male specimen available for study was missing the metasoma, so additional diagnostic characters on the metasoma may exist.

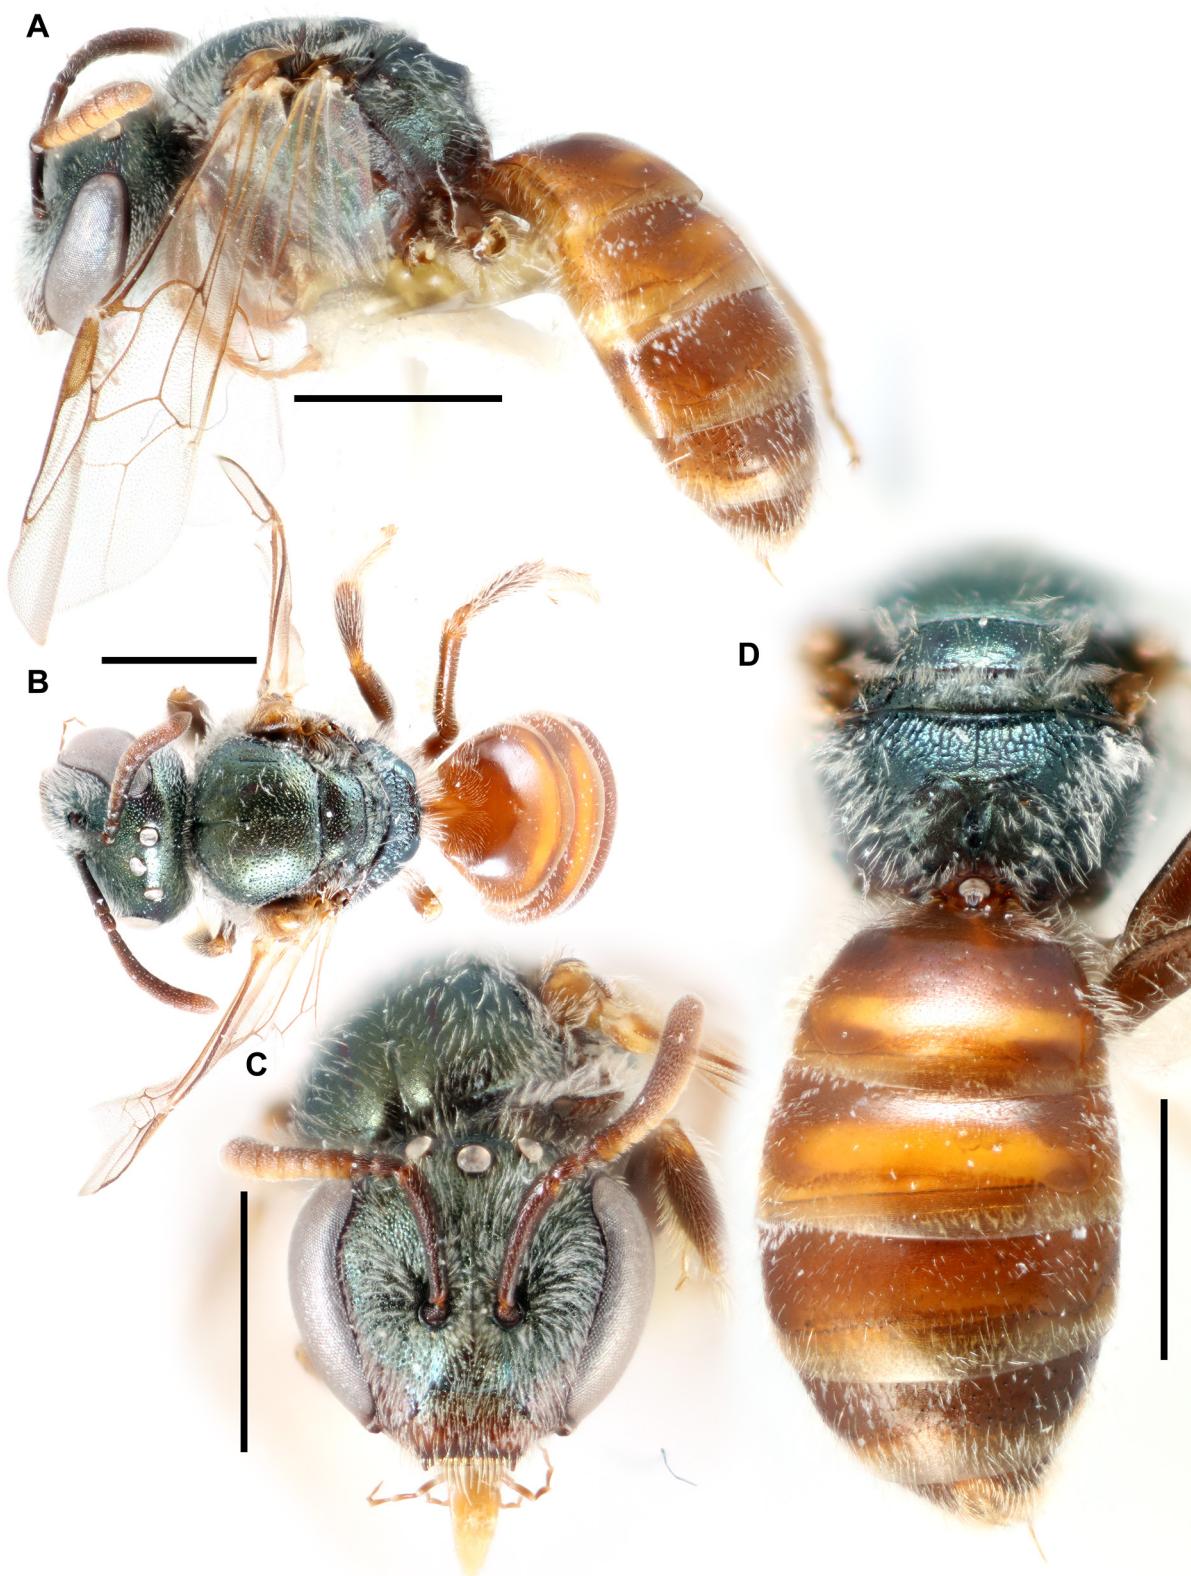

Fig. 67. *Lasioglossum (D.) surianae* (Mitchell, 1960), ♀ (PCYU). **A.** Lateral habitus. **B.** Dorsal habitus. **C.** Face. **D.** Metasoma and propodeum. Scale bars = 1 mm.

Males of *L. surianae* are most similar to those of *L. deludens* sp. nov., *L. diabolicum* sp. nov., *L. rufodeludens* sp. nov., and *L. perparvum*, all of which (except *L. perparvum*) have the face entirely covered with dense tomentum below the eye emargination. In addition, males of *L. deludens* and *L. rufodeludens* have the tegula impunctate except on extreme anterior margin. Males of *L. perparvum* have the clypeus with some sparse tomentum and tegula usually dark brown.

Etymology

Mitchell (1960) named this species after the plant *Suriana maritima* L., one of its hosts.

Fig. 68. *Lasioglossum (D.) surianae* (Mitchell, 1960), ♂ (reproduced from Gibbs 2011) (UCFC). **A.** Lateral habitus. **B.** Face. **C.** Mesonotum. Scale bars = 1 mm.

Range

Florida and Bahamas (Fig. 69).

Floral hosts (from Mitchell 1960 and Gibbs 2011)

ASTERACEAE: *Bidens*: *B. pilosa* • CONVOLVULACEAE: *Jacquemontia* Choisy • SURIANACEAE Arn.: *Suriana* L.: *S. maritima* L.

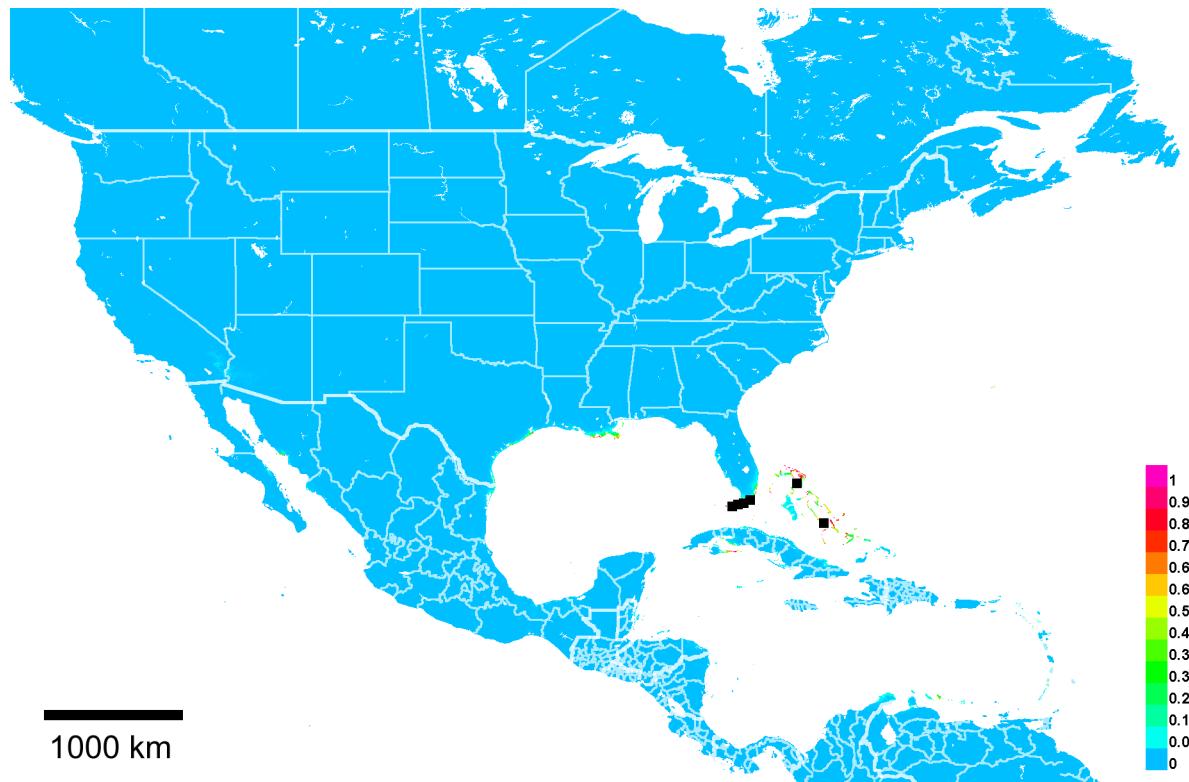

Fig. 69. Georeferenced collection records of *Lasioglossum (D.) surianae* (Mitchell, 1960) (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence. Because many coastal records lacked soil data, the model was generated without soil type as an environmental variable.

DNA barcodes

One confirmed sequence available (BOLD process ID: BEECB173-07). It is closest in terms of p-distance to *L. pseudotegulare* (4.29% minimum interspecific p-distance). Nine fixed nucleotide substitutions distinguish *L. surianae* from all other Nearctic species of the *L. gemmatum* complex: 15(A), 105(C), 123(C), 276(C), 288(G), 358(C), 399(C), 420(T), and 564(T) ([Supp. file 2](#)).

Diagnosis

Females of *L. tegulare* have the tegula relatively small (reaching but not exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin weakly concave and a narrowly rounded posterior projection smaller than 0.5 OD, and densely (IS < 1 PD) to moderately densely punctate (IS = 1–2 PD); mesoscutum and mesepisternum very dull, strongly tessellate, imbricate, or rugulose; mesepisternum punctures crowded (IS = 0 PD) and indistinct; metapostnotum with strong, coarse rugae reaching posterior margin and covering propodeum dorsolateral slope, shiny in basal half; face short (length/width ratio usually ≤ 0.83); T2–T4 flat in lateral view; T3 without subapical tomentum; and head and mesosoma usually olive green.

Females of *L. tegulare* are most similar to those of *L. coactus*, *L. ellisiae*, *L. holzenthalii* sp. nov., and *L. puteulanum*. Females of *L. coactus* have T2–T4 convex in lateral view and T3 with dense and complete subapical band of tomentum. Females of *L. ellisiae* have the mesepisternum punctures distinctly separated and round, and the mesoscutum posterior half and mesepisternum often shiny. Females of *L. holzenthalii* have the mesepisternum punctures distinctly separated (up to 1 PD) and metapostnotum rugae not extending onto propodeum dorsolateral slope. Females of *L. puteulanum* have the face longer (length/width ratio usually > 0.83), tegula more sparsely punctate (IS = 1–2 PD, closer to 2 PD), and head and mesosoma usually blue (rarely olive green).

Males of *L. tegulare* have the tegula relatively small (as in the female); mesoscutum relatively coarsely and moderately densely punctate (IS = 1–2 PD); metapostnotum shiny with strong subparallel rugae; discs of T1–T2 and premarginal line uniformly densely punctate (IS ≤ 1 PD); face with sparse tomentum below eye emargination, more concentrated in paraocular area; and head and mesosoma usually olive green.

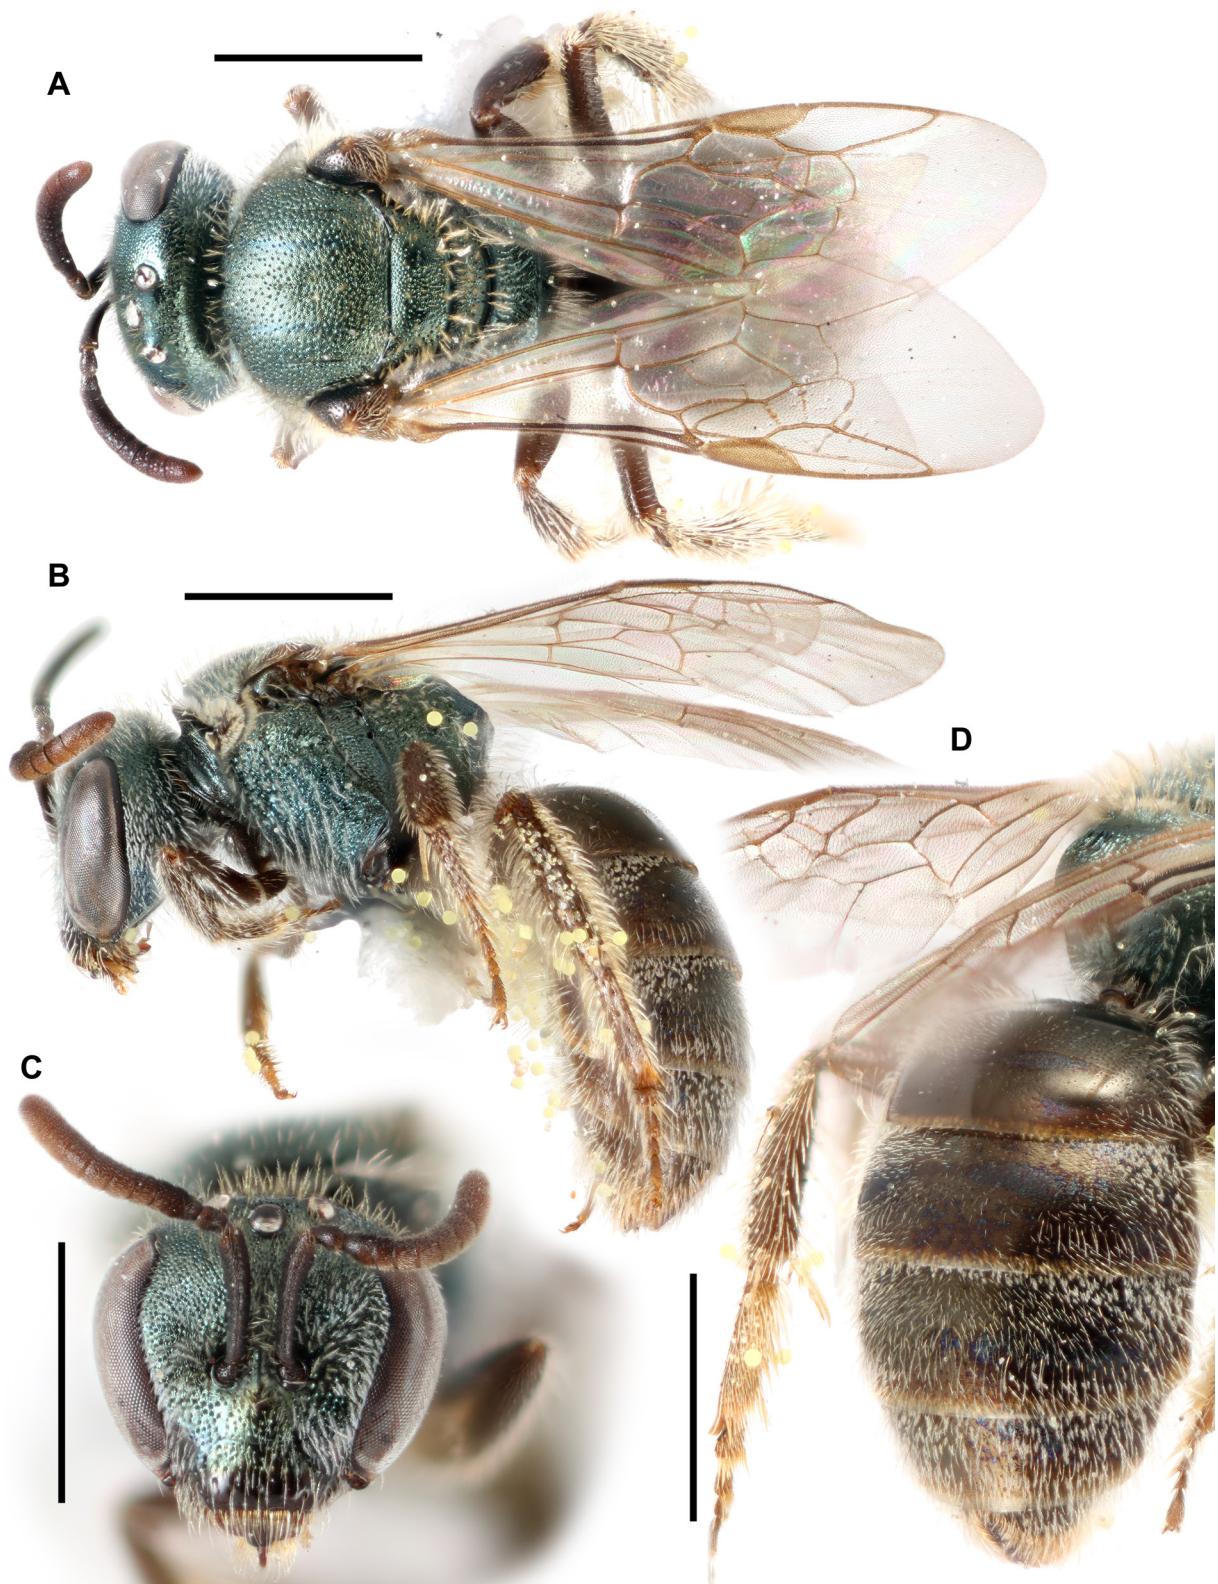

Fig. 70. *Lasioglossum (D.) tegulare* (Robertson, 1890), ♀. **A.** Dorsal habitus. **B.** Lateral habitus. **C.** Face. **D.** Metasoma. Scale bars = 1 mm.

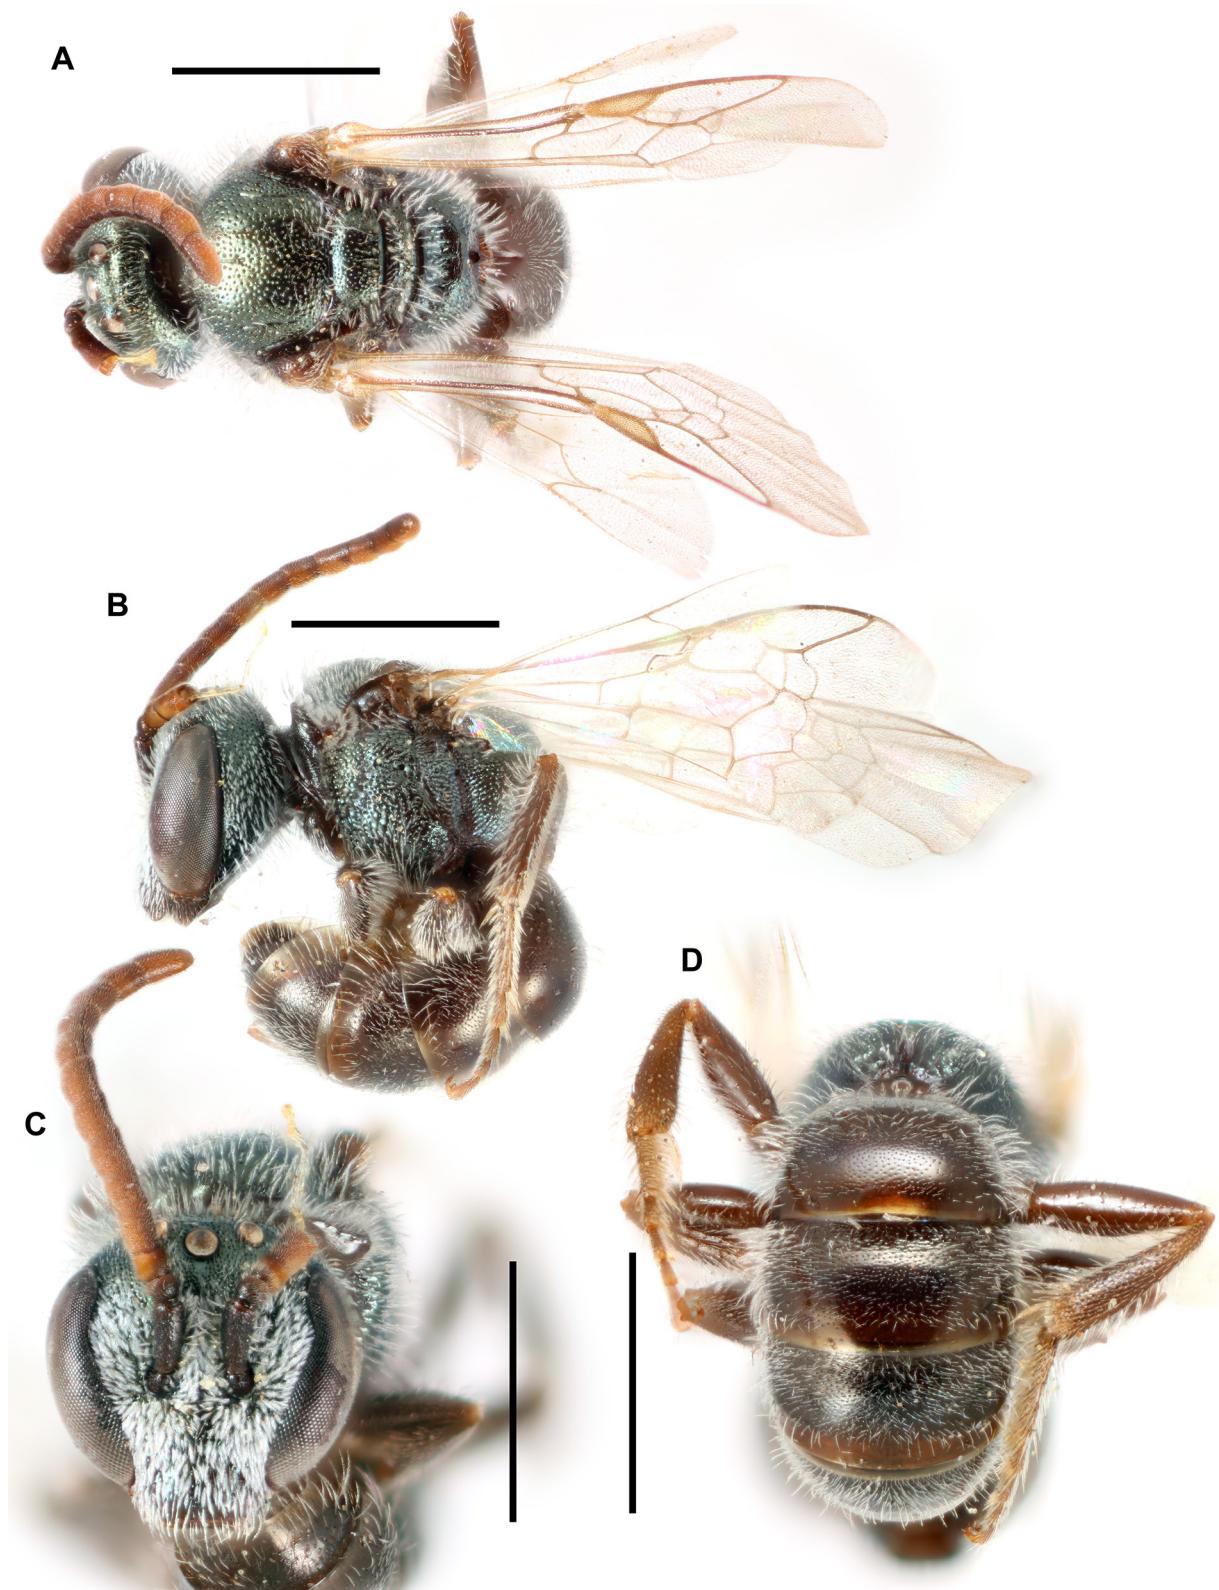

Fig. 71. *Lasioglossum (D.) tegulare* (Robertson, 1890), ♂ (TAMU). **A.** Dorsal habitus. **B.** Lateral habitus. **C.** Face. **D.** Metasoma. Scale bars = 1 mm.

Males of *L. tegulare* are most similar to those of *L. coactus*, *L. ellisiae*, and *L. puteulanum*. Males of *L. coactus* have the discs of T1–T3 even more densely punctate (IS < 1 PD) and strongly convex, and apical rims abruptly and deeply depressed. Males of *L. ellisiae* have the mesoscutum usually more finely and densely punctate laterally (IS < 1 PD) and disc of T2 becoming more sparsely punctate near and on premarginal line (IS = 1–2 PD). Males of *L. puteulanum* have the face below eye emargination evenly covered in tomentum, tegula more sparsely punctate (IS = 1–3 PD), and the head and mesosoma usually blue to blue-green.

Etymology

Robertson (1890) formed the specific epithet ‘*tegularis*’ from the Latin noun ‘*tegula*’ (roof tile, literally ‘covering instrument’, now applied to the sclerite covering the wing base), and the adjectival suffix ‘-aris’ (of or pertaining to).

Range

Eastern United States and Canada (Fig. 72).

Floral hosts

APIACEAE: *Bifora* Hoffm. • *Ptilimnium* Raf. • ASTERACEAE: *Aster* • *Eupatorium* L. • *Helianthus*: *H. annuus* • *Rudbeckia*: *R. bicolor* Nutt. • BRASSICACEAE: *Physaria*: *P. filiformis* (Rollins) O’Kane & Al-Shehbaz • EUPHORBIACEAE: *Croton* • FABACEAE: *Cassia* • *Lupinus*: *L. texensis* • *Melilotus*: *M. officinalis*: *M. o.* subsp. *alba* • FAGACEAE Dumort.: *Castanea* Mill. • LAMIACEAE: *Mentha* • *Monarda* • MALVACEAE: *Gossypium* • SCROPHULARIACEAE: *Leucophyllum*: *L. frutescens*.

DNA barcodes

Twenty-three confirmed sequences available (BOLD process IDs: DIAL091-06, DIAL485-06, DIAL490-06, DIAL491-06, DIAL493-06, DIAL495-06, DIAL518-06, DIAL683-06, DIAL684-06, DIAL742-06, DIAL743-06, DIAL744-06, DIAL745-06, DIAL824-06, DIAL1050-06, DIAL1051-06, DLII061-06, DLII468-07, DLII1300-08, DLII1331-08, DLII1356-08, DLII1545-09, LASNA006-08). There is a large amount of divergence within these sequences (1.58% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. puteulanum* (0.31% minimum interspecific p-distance). No fixed nucleotide substitutions distinguish *L. tegulare* from all other species of the *L. gemmatum* complex or closely related species.

Comments

Robertson (1890) included Montana, California, and Mexico specimens in the type series. These must constitute other species in the *L. gemmatum* complex, but were not examined in this study. Cresson (1928) subsequently designated a Connecticut specimen from the type series as the name-bearing type.

Lasioglossum (Dialictus) tegulariforme (Crawford, 1907)

Figs 73–75, 76P, 88B, 90A, 93A, 108A, 109A

Halictus (Chloralictus) tegulariformis Crawford, 1907: 194 (holotype, ♀, deposited in USNM, examined).

Halictus tegulariformis – Cockerell 1916: 77 (comparative notes to *helianthi*).

Halictus (Chloralictus) tegulariformis – Ellis 1914: 101 (comparison to *jamaicae* = *gemmatum*). — Sandhouse 1924: 2, 7 (key to species), 11 (comparison to *ellisiae*).

Lasioglossum (Chloralictus) tegulariforme – Michener 1951: 1118 (catalogue).

Dialictus tegulariformis – Hurd 1979: 1972 (catalogue). — Moure & Hurd 1987: 133 (catalogue).

Diagnosis

Females of *L. tegulariforme* have the tegula very large (maximum length more than half ITS and clearly exceeding posterior margin of mesoscutum in dorsal view), with inner posterior margin strongly concave, and densely punctate (IS < 1 PD); T1 disc with an impunctate median line about 1 OD wide; paraocular area punctures similar in size and density to frons punctures; mesoscutum completely dull, tessellate, and finely and densely punctate (IS ≤ 1 PD with 4–5 punctures between posterior end of parapsidal line and lateral edge of mesoscutum); T1 anterior slope usually somewhat shiny with weak microsculpture; and T3 usually with a dense and complete subapical band of tomentum.

Females of *L. tegulariforme* are most similar to those of *L. angelicum* sp. nov., *L. gaudiale*, and *L. helianthi*, all of which have the T1 disc uniformly punctate, paraocular punctures distinctly larger and sparser than frons punctures, and T3 lacking a complete subapical band of tomentum. Females of *L. gaudiale* (and most *L. angelicum*) also have the mesoscutum more sparsely punctate (IS = 1–2 PD and 2–3 punctures between posterior end of parapsidal line and lateral edge of mesoscutum) and often shiny. Females of *L. helianthi* have the tegula smaller (maximum length half or less ITS and not exceeding posterior margin of mesoscutum in dorsal view).

Males of *L. tegulariforme* have the tegula large (as in the female); mesoscutum tessellate and densely punctate (IS ≤ 1 PD); metapostnotum shiny with strong rugae; disc of T1 finely, sparsely punctate medially (IS = 1–3 PD), contrasting with the more densely punctate disc of T2 (IS = 1–2 PD); and T1–T2 apical rims impunctate.

Males of *L. tegulariforme* are most similar to those of *L. angelicum* sp. nov. and *L. helianthi*, both of which have the T1–T2 discs uniformly moderately densely to sparsely punctate (IS = 1–2 PD) with some punctures extending onto apical rims. In addition, males of *L. angelicum* have the mesoscutum usually more sparsely punctate (IS = 1–2 PD), and males of *L. helianthi* have the tegula smaller (not exceeding posterior margin of mesoscutum in dorsal view).

Etymology

Crawford (1907) formed the specific epithet ‘*tegulariformis*’ from the specific epithet ‘*tegularis*’ plus the Latin noun ‘*forma*’ (shape, figure) and the adjectival suffix ‘-is’ (pertaining to, having the nature of). It refers to the similarity of this species to *L. tegulare*.

DNA barcodes

Three confirmed sequences available (BOLD process IDs: BCLRB752-10, DLIII111-18, DLIII112-18). There is a small amount of divergence within these sequences (0.31% maximum intraspecific p-distance). They are closest in terms of p-distance to *L. deludens* sp. nov. (2.17% minimum interspecific p-distance). Two fixed nucleotide substitutions distinguish *L. tegulariforme* from all other Nearctic species of the *L. gemmatum* complex: 183(T) and 570(C) ([Supp. file 2](#)).

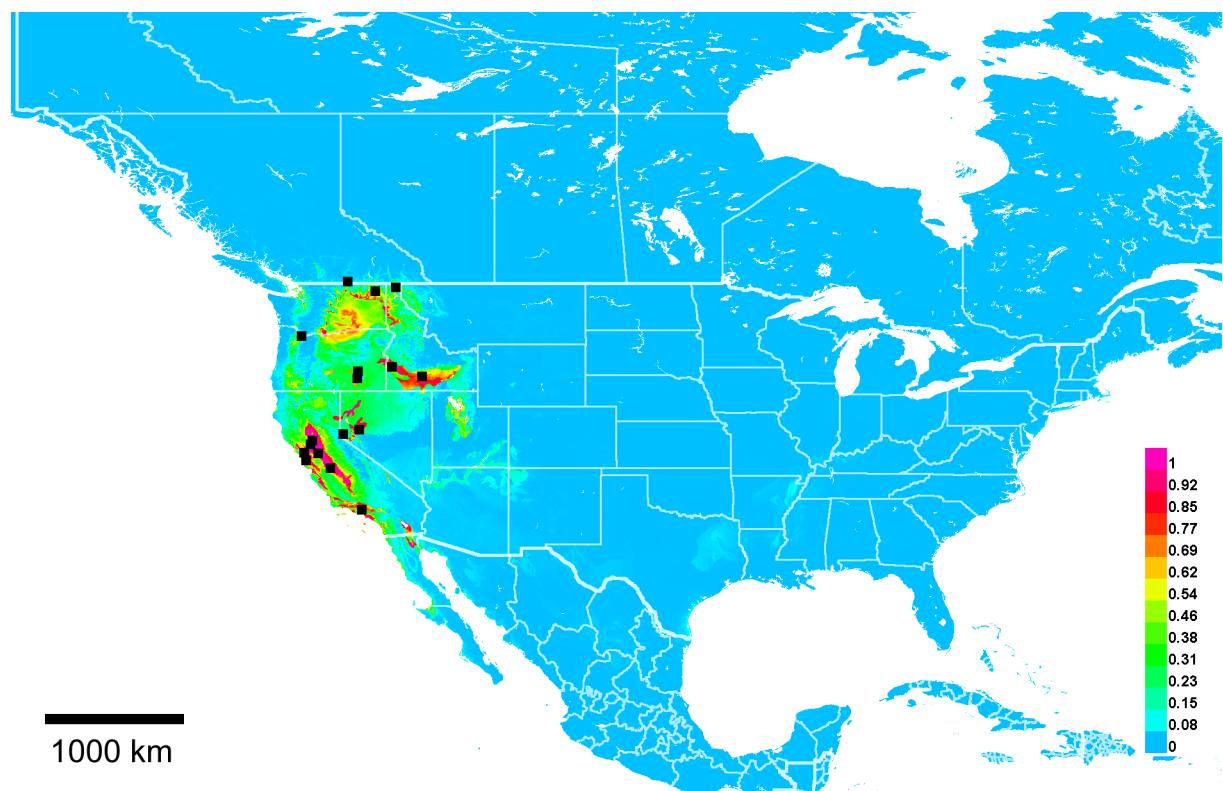

Fig. 75. Georeferenced collection records of *Lasioglossum (D.) tegulariforme* (Crawford, 1907) (black squares) and predicted distribution by maximum entropy ecological niche modelling in Maxent (colour shading). Warmer colours indicate higher cloglog probability of occurrence.

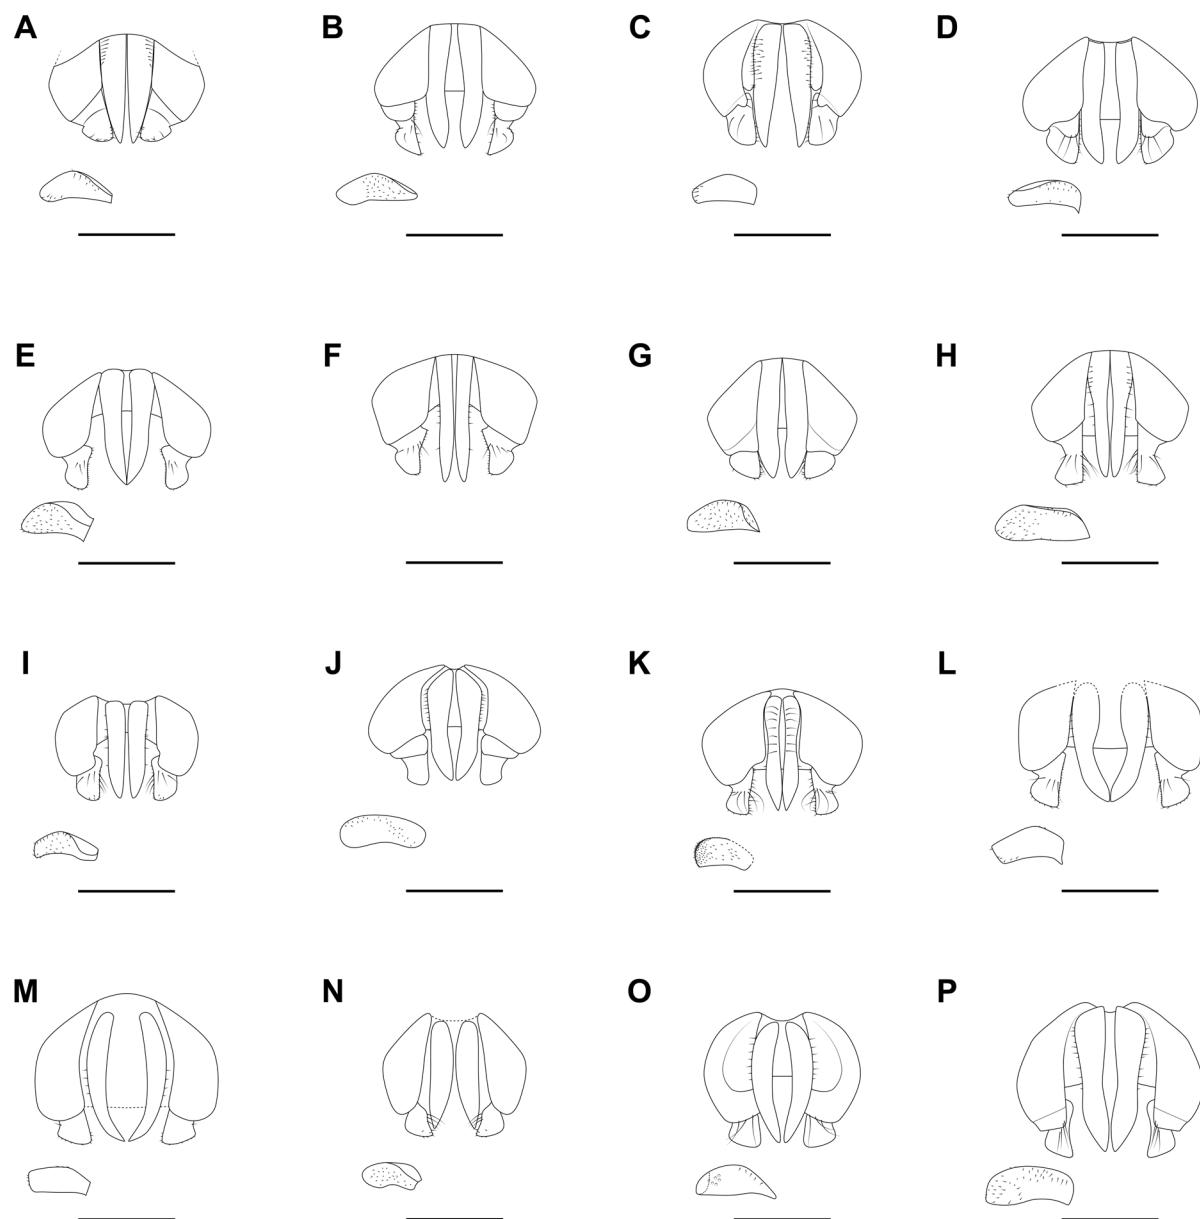

Fig. 76. Male genitalia illustrated in dorsal view and positioned such that the gonostylus is parallel to the plane of vision. Retrorse lobes are also illustrated separately to the bottom left of each figure in lateral view, positioned parallel to the plane of vision. **A.** *Lasioglossum (D.) angelicum* sp. nov. **B.** *L. (D.) coactus* (Cresson, 1872). **C.** *L. (D.) deludens* sp. nov. **D.** *L. (D.) diabolicum* sp. nov. **E.** *L. (D.) gaudiale* (Sandhouse, 1924). **F.** *L. (D.) gloriosum* sp. nov. (the retrorse lobe was not visible for illustration). **G.** *L. (D.) helianthi* (Cockerell, 1916). **H.** *L. (D.) holzenthalii* sp. nov. **I.** *L. (D.) indagator* sp. nov. **J.** *L. (D.) magnitegula* sp. nov. **K.** *L. (D.) perparvum* (Ellis, 1914). **L.** *L. (D.) profoundum* sp. nov. **M.** *L. (D.) pseudotegulare* (Cockerell, 1896). **N.** *L. (D.) rufodeludens* sp. nov. This genital capsule was damaged during dissection and some details may be slightly distorted. **O.** *L. (D.) stictaspis* (Sandhouse, 1923) (holotype) (reproduced from Gardner & Gibbs 2022). **P.** *L. (D.) tegulariforme* (Crawford, 1907) (reproduced from Gardner & Gibbs 2022). Scale bars = 0.25 mm.

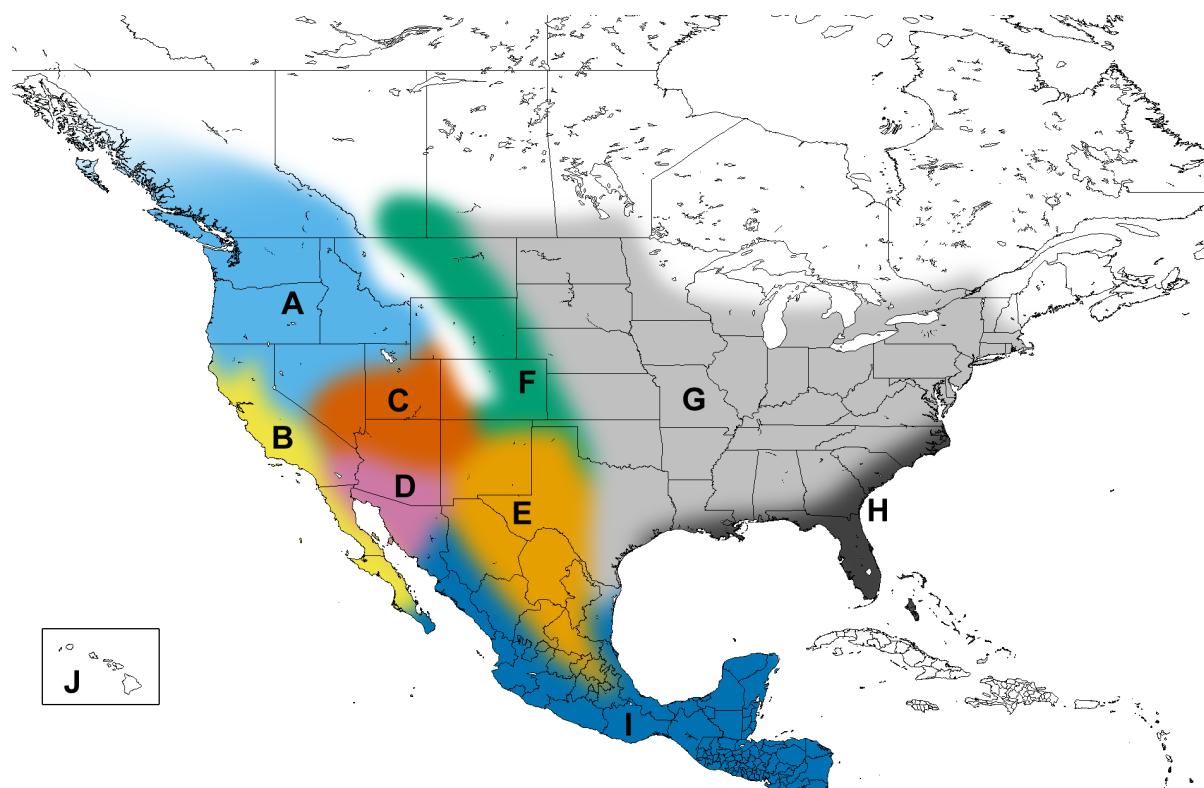

Fig. 77. Major geographic regions with distinct *Lasioglossum gemmatum* species complex fauna. Borders are intentionally blurred because the limits of these regions are approximate and spillover near transition zones is well-known. **A.** Cascadia (also including northern Great Basin). **B.** California. **C.** High desert (including southern Great Basin, Mojave Desert, and Colorado Plateau). **D.** Western low desert (including Sonoran Desert and western Chihuahuan Desert). **E.** Eastern low desert (including most of Chihuahuan Desert). **F.** Western Great Plains. **G.** Eastern. **H.** Southeastern. **I.** Neotropical. **J.** Hawaii.

Table 2. List of species of *L. gemmatum* complex associated with major geographic regions defined in Fig. 77. These lists should not be considered absolutely inclusive but should be reliable near the centre of each region and become slightly less inclusive nearer to transition zones. Species marked with an asterisk occur primarily at high elevations or sky islands within the given regions.

Region	Associated species
Cascadia	<i>L. helianthi</i> , <i>L. tegulariforme</i>
California	<i>L. angelicum</i> sp. nov., <i>L. deludens</i> sp. nov., <i>L. gaudiale</i> , <i>L. helianthi</i> , <i>L. perparvum</i> , <i>L. tegulariforme</i>
High desert	<i>L. deludens</i> sp. nov., <i>L. diabolicum</i> sp. nov., <i>L. eremum</i> sp. nov. *, <i>L. gaudiale</i> , <i>L. gloriosum</i> sp. nov.
Western low desert	<i>L. deludens</i> sp. nov., <i>L. diabolicum</i> sp. nov., <i>L. gaudiale</i> , <i>L. indagator</i> sp. nov., <i>L. holzenthalii</i> sp. nov. *, <i>L. perparvum</i> , <i>L. pseudotegulare</i> , <i>L. stictaspis</i>
Eastern low desert	<i>L. coactus</i> , <i>L. deludens</i> sp. nov., <i>L. ellisiae</i> , <i>L. eremum</i> sp. nov. *, <i>L. gaudiale</i> , <i>L. indagator</i> sp. nov., <i>L. holzenthalii</i> sp. nov. *, <i>L. perparvum</i> , <i>L. profundum</i> sp. nov., <i>L. stictaspis</i>
Western Great Plains	<i>L. coactus</i> , <i>L. ellisiae</i> , <i>L. eremum</i> sp. nov. *, <i>L. gaudiale</i> , <i>L. stictaspis</i>
Eastern	<i>L. carlinvillense</i> , <i>L. coactus</i> , <i>L. ellisiae</i> , <i>L. rufodeludens</i> sp. nov., <i>L. tegulare</i>
Southeastern	<i>L. lepidii</i> , <i>L. puteulanum</i> , <i>L. suriana</i>
Neotropical	<i>L. holenthalii</i> sp. nov. *, <i>L. magnitegula</i> sp. nov., <i>L. pseudotegulare</i> , <i>L. rufodeludens</i> sp. nov., <i>L. stictaspis</i> , numerous undescribed species
Hawaii	<i>L. helianthi</i> , <i>L. puteulanum</i>

Keys

This is a challenging complex, so efforts should be made to ensure the specimen is well-prepared. It is helpful to examine long series of specimens (if available) to mitigate difficulties caused by rare, unusual variation. Geographical data are useful for helping discriminate species (see Fig. 77 and Table 2), but readers should refer back to species diagnoses and descriptions to verify their identifications.

Key to Nearctic *Lasioglossum* groups with enlarged tegula

1. Head and mesosoma black to brown 2
- Head and mesosoma metallic golden, green, or blue 3
2. Mesepisternum rugose *L. (Hemihalictus) kincaidii* (Cockerell, 1898)
- Mesepisternum imbricate *L. (Hemihalictus) glabriventre* (Crawford, 1907)
3. Metasoma with no appressed tomentum in either sex (but with abundant simple setae); S2–S4 with long (2–4 OD), dense, scopa-like pubescence in males *L. (Dialictus) knereri* Gibbs, 2010 (atypical forms only known from California)
- Metasoma with some appressed tomentum at least on T2–T3 basolateral areas in females; S2–S4 with shorter (1–2 OD) and sparser pubescence in males, not scopa-like 4
4. T1 with lateral tomentum (except in some males); clypeus projecting more than 50% below suborbital tangent; propodeum oblique carina absent in both sexes *L. (Dialictus) perdifficile* species complex
- T1 without lateral tomentum in either sex; clypeus projecting about 50% below suborbital tangent; propodeum oblique carina present in females (but may be fine and difficult to distinguish from background surface sculpture) *L. (Dialictus) gemmatum* species complex

Key to females

1. Mesoscutum with appressed, fine, stubble-like setae less than 0.25 OD long, appearing shaved, and erect plumose setae about 1 OD long or less, these setae very sparse (each seta separated by about its length from the one nearest it, with some gaps about a seta's length wide visible in lateral view) (Fig. 78A–B); mesoscutum golden-green to coppery, contrasting with blue to blue-green propodeum; size very small (ITS 0.67–0.77 mm); metasoma black 2
- Mesoscutum with appressed, fine setae 0.25–0.5 OD long and erect plumose setae about 1 OD long, these setae dense (each seta within its length from the one nearest it, with no gaps wider than half a seta's length visible in lateral view) (Fig. 78C–D); mesoscutum usually concolourous with propodeum; size larger (ITS normally >0.77 mm, except in *L. gloriosum* sp. nov., *L. indagator* sp. nov., and *L. rufodeludens* sp. nov., in which the metasoma is red-orange) 3
2. Tegula sparsely punctate (IS = 1–4 PD) at least laterally, not exceeding posterior margin of mesoscutum in dorsal view, with inner posterior margin straight, coming to a blunt angle posteriorly (Fig. 79A); apical rims of T1–T3 minutely punctate (Fig. 80A) (deserts of southern United States and northern Mexico) ***L. perparvum* (Ellis, 1914)**
- Tegula densely punctate (IS <1 PD), exceeding posterior margin of mesoscutum in dorsal view by almost 1 OD, with inner posterior margin concave and a rounded projection reaching axilla posteriorly (Fig. 79B); apical rims of T1–T3 impunctate (Fig. 80B) (Neotropical Mexico, rarely occurring north to United States border) ***L. magnitegula* sp. nov.**

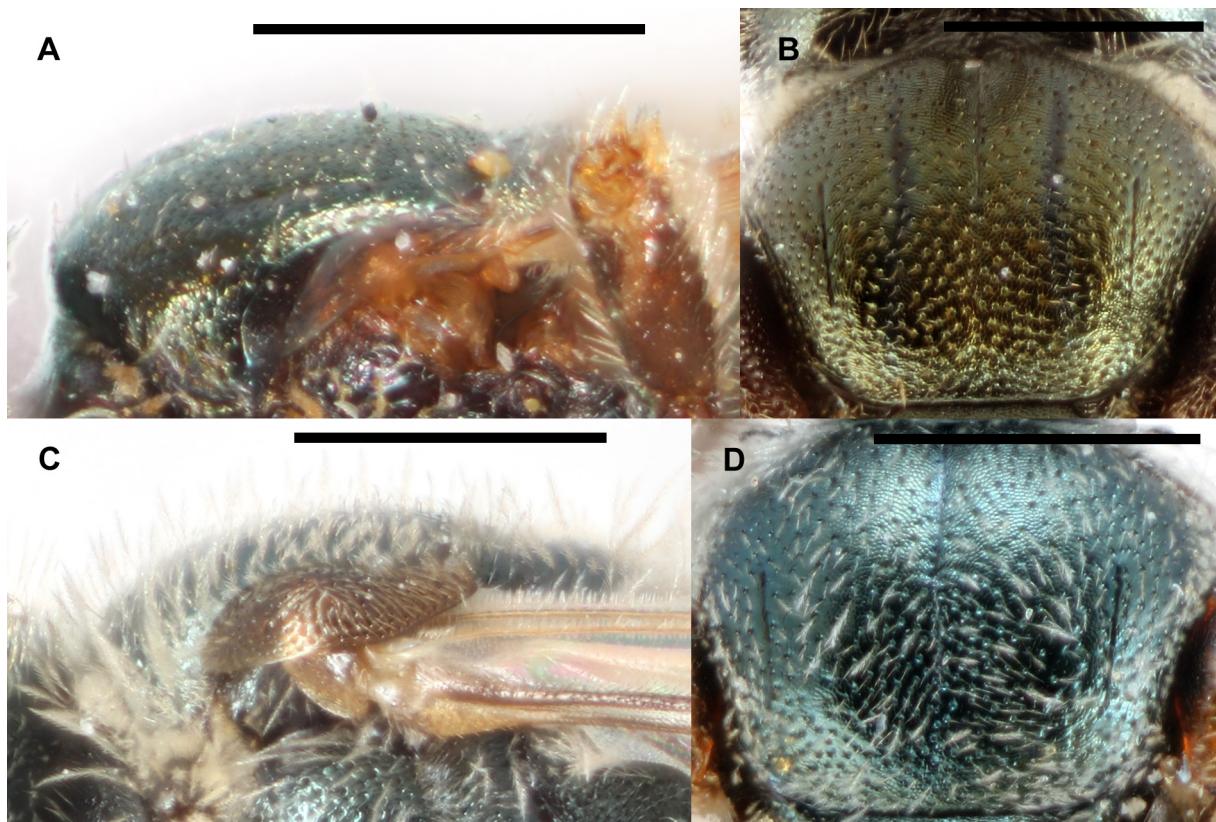

Fig. 78. Mesoscutum pubescence. **A.** *Lasioglossum perparvum* (Ellis, 1914), ♀, lateral view, with pubescence very short and sparse. **B.** *L. magnitegula* sp. nov., ♀, dorsal view, with pubescence very short and sparse. **C.** *L. angelicum* sp. nov., ♀, lateral view, with pubescence long and dense. **D.** *L. deludens* sp. nov., ♀, dorsal view, with pubescence long and dense. Scale bars = 0.5 mm.

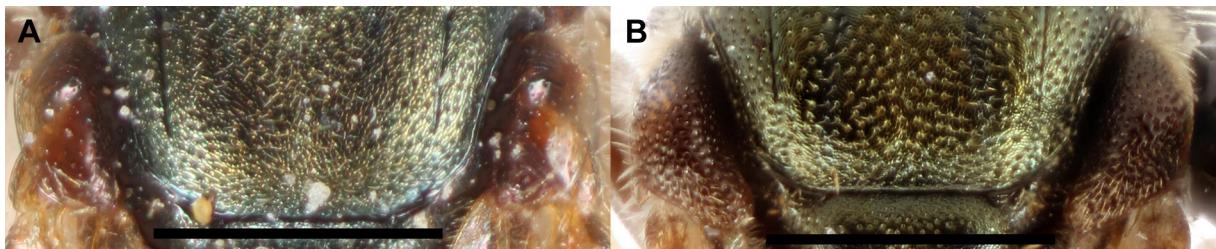

Fig. 79. Tegulae. **A.** *Lasioglossum perparvum* (Ellis, 1914), ♀, sparsely punctate, not exceeding posterior margin of mesoscutum, and inner posterior margin straight. **B.** *L. magnitegula* sp. nov., ♀, densely punctate, exceeding posterior margin of mesoscutum, and inner posterior margin concave. Scale bars = 0.5 mm.

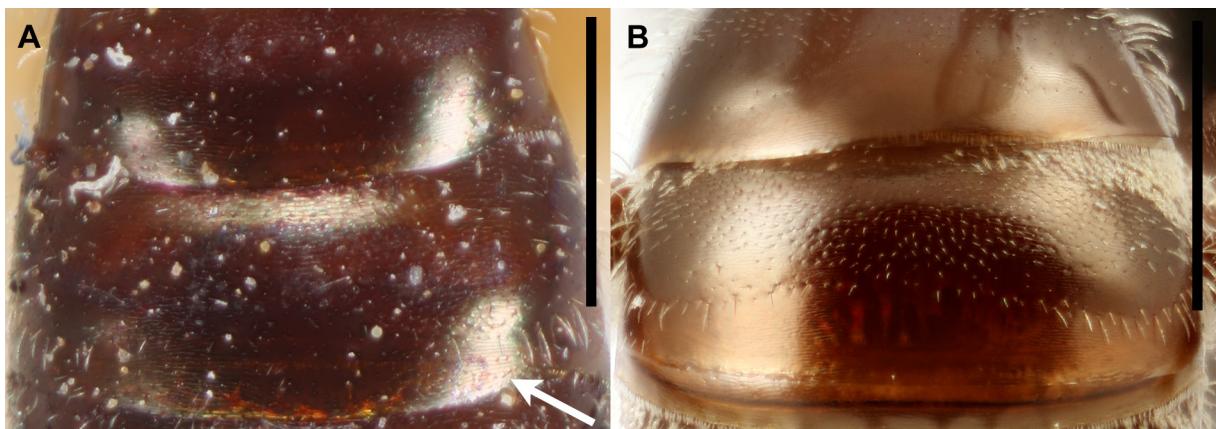

Fig. 80. T1–T2 apical rims. **A.** *Lasioglossum perparvum* (Ellis, 1914), ♀, apical rims with some fine punctures and short setae (arrow). **B.** *L. magnitegula* sp. nov., ♀, apical rims impunctate and glabrous. Scale bars = 0.5 mm.

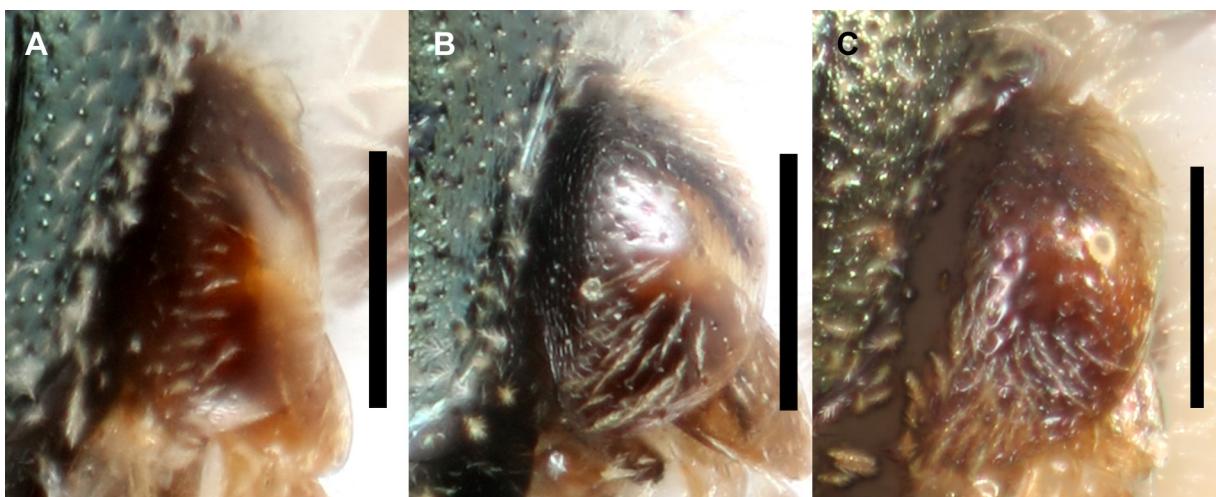

Fig. 81. Tegula. **A.** *Lasioglossum profundum* sp. nov., ♀, impunctate. **B.** *L. holzenthalii* sp. nov., ♀, sparsely punctate. **C.** *L. stictaspis* (Sandhouse, 1923), ♀, densely punctate. Scale bars = 0.25 mm.

3. Tegula impunctate except on extreme anterior margin (Fig. 81A) 4
 – Tegula with at least a few distinct punctures medially, usually many (Fig. 81B–C) 7
4. Tegula dark brown; mesoscutum coarsely punctate (punctuation similar to mesepisternum)
 *L. profundum* sp. nov.
 – Tegula yellow-orange; mesoscutum more finely punctate (punctures smaller than those of mesepisternum) 5
5. Mesoscutum and mesepisternum completely dull, tessellate to imbricate; metasoma entirely red-orange (eastern Texas, Nuevo Leon, and Tamaulipas) *L. rufodeludens* sp. nov.
 – Mesoscutum lateral and posterior margins and/or mesepisternum shiny with at most weak microsculpture (rarely both dull); at least basal half of discs of metasomal terga reddish brown to black (apical areas may be red-orange or black) 6
6. Postgena smooth and shiny (as in Fig. 82A) (Chihuahuan and Sonoran Deserts)
 *L. deludens* sp. nov.
 – Postgena dull, lineolate (as in Fig. 82B) (Florida Keys and Bahamas)
 *L. surianae* (Mitchell, 1960) [in part]
7. Mesoscutum, preepisternum, mesepisternum, and hypoepimeron margins fringed with appressed tomentum (Fig. 83A); metepisternum covered in dense tomentum obscuring the surface; metanotum median third covered in dense pubescence obscuring the surface (Fig. 83A); tegula and metasoma bright red-orange 8
 – Mesoscutum and pleura without appressed tomentum (except sometimes mesoscutum anterolateral margins or metepisternum with sparse tomentum not obscuring the surface) (Fig. 83B); metanotum with dense pubescence limited to anterior margin (Fig. 83B); tegula and metasoma usually black to brown (if red-orange, then lacking the other characters) 9

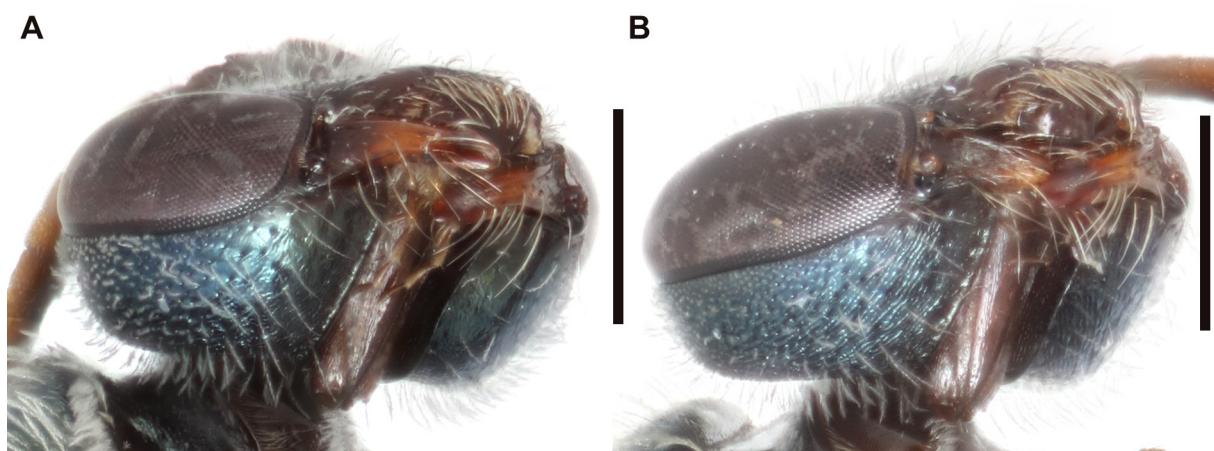

Fig. 82. Ventral surface of head showing postgena. **A.** *Lasioglossum profundum* sp. nov., ♀, smooth and shiny. **B.** *L. coactus* (Cresson, 1872), ♀, dull and lineolate. Scale bars = 0.5 mm.

8. Mesepisternum with most punctures separated by half a puncture diameter or less (IS < 0.5 PD) (Fig. 84A); tegula outer margin densely punctate (IS ≤ 1 PD) (Nevada, Utah, and northern New Mexico) *L. gloriosum* sp. nov.
- Mesepisternum with most punctures separated by up to one puncture diameter or slightly more (IS ≤ 1 PD) (Fig. 84B); tegula outer margin sparsely punctate (IS = 1–3 PD) (southern Arizona, New Mexico, and Texas) *L. indagator* sp. nov.

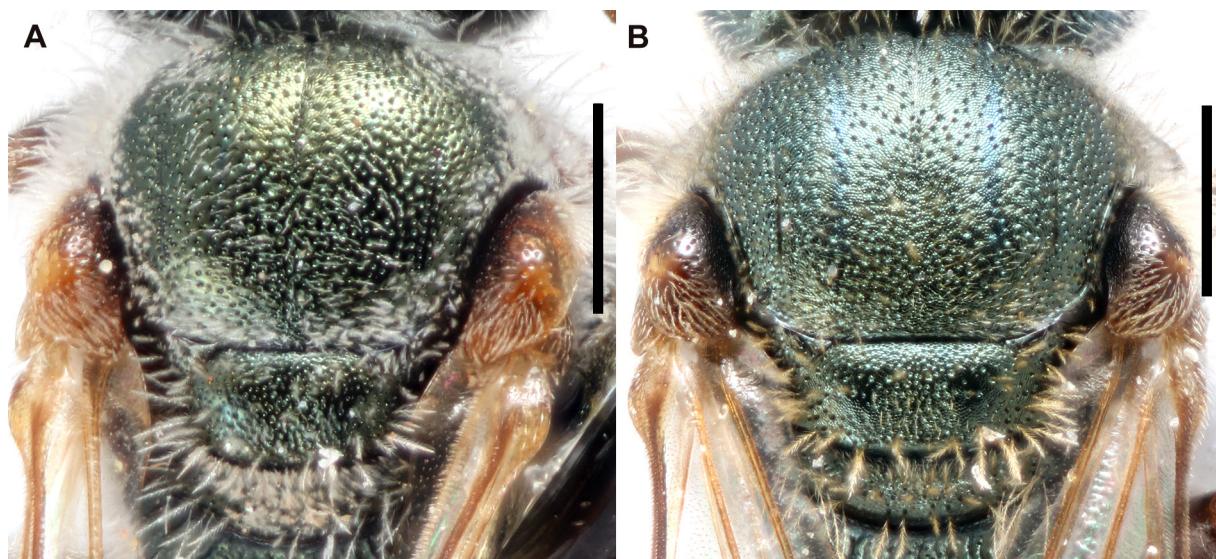

Fig. 83. Mesonotum. **A.** *Lasioglossum gloriosum* sp. nov., ♀, with dense tomentum on metanotum and margins of mesoscutum. **B.** *L. tegulare* (Robertson, 1890), ♀, with sparse tomentum. Scale bars = 0.5 mm.

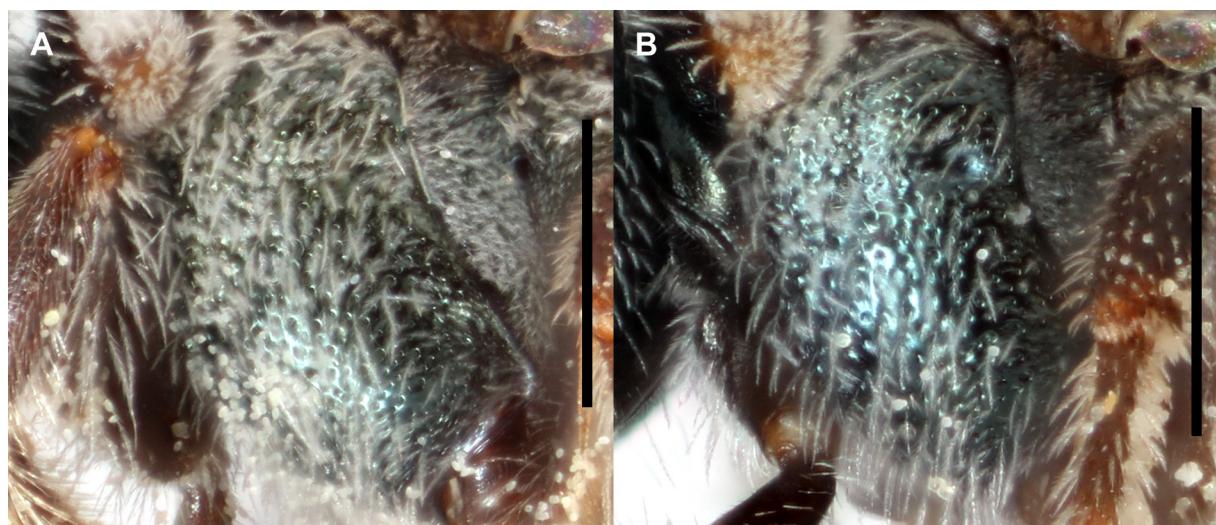

Fig. 84. Mesepisternum. **A.** *Lasioglossum gloriosum* sp. nov., ♀, with punctures very dense (IS ≤ 0.5 PD). **B.** *L. indagator* sp. nov., ♀, with punctures sparser (IS ≤ 1 PD). Scale bars = 0.5 mm.

9. T2–T3 usually each slightly convex with apical rim distinctly downcurved in lateral view (Fig. 85A); T3 usually with dense and complete subapical band of tomentum (Fig. 86A); disc of T2 with deep and dense punctures ($IS \leq 1$ PD) reaching premarginal line and contrasting with largely impunctate apical rim (Fig. 86A) (Colorado to Veracruz) *L. coactus* (Cresson, 1872)
- T2–T3 each flat in lateral view and apical rim continuous with contour of disc (Fig. 85B); T3 without subapical band of tomentum or this band sparse and broadly interrupted medially (except in *L. stictaspis* and *L. tegulariforme*, in which the disc of T2 has finer and sparser punctures ($IS = 1–3$ PD) either becoming inconspicuous near premarginal line or extending onto apical rim) (Fig. 86B) 10

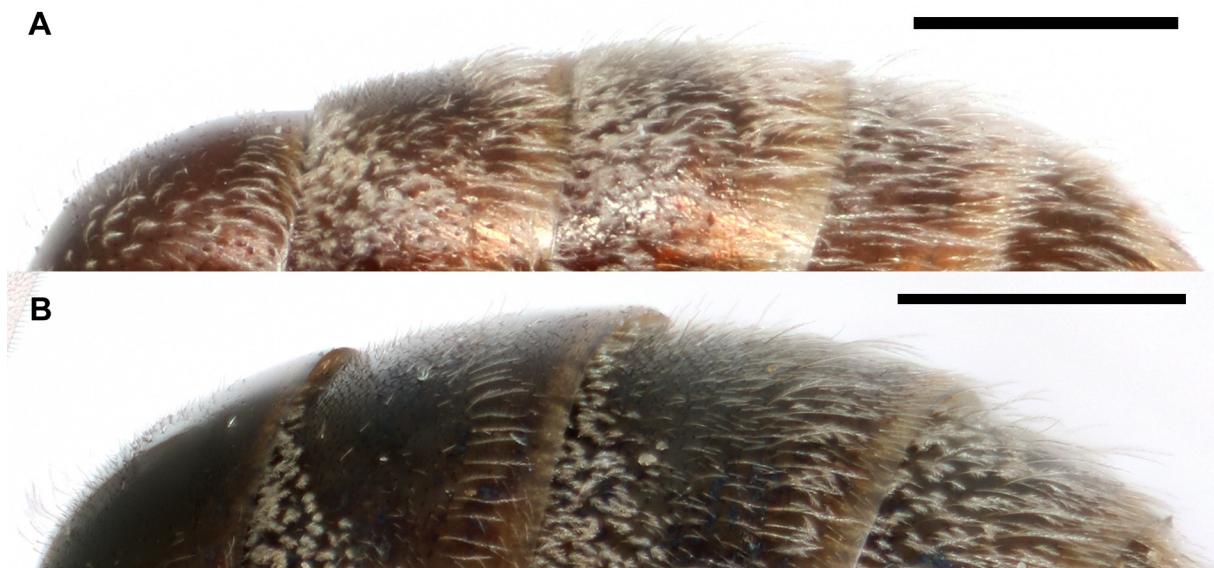

Fig. 85. Metasomal terga. **A.** *Lasioglossum coactus* (Cresson, 1872), ♀, with T2–T3 each slightly convex and apical rim downcurved in lateral view. **B.** *L. tegulare* (Robertson, 1890), ♀, with T2–T3 each flat and apical rim continuous with contour of disc in lateral view. Scale bars = 0.5 mm.

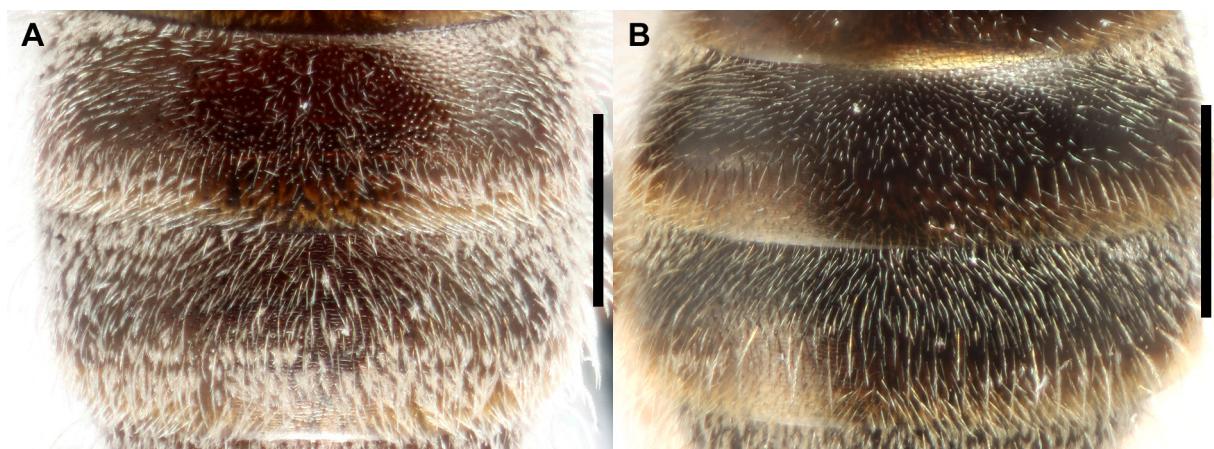

Fig. 86. T2–T3. **A.** *Lasioglossum coactus* (Cresson, 1872), ♀, with complete subapical band of tomentum on T3 and deep and dense punctures on disc of T2 contrasting with sparsely punctate apical rim. **B.** *L. angelicum* sp. nov., ♀, T3 without complete subapical band of tomentum and fine T2 punctures not contrasting across premarginal line. Scale bars = 0.5 mm.

10. Tegula relatively large (maximum length more than half ITS and reaching or exceeding posterior margin of mesoscutum in dorsal view), densely punctate throughout (IS < 1 PD), and usually with inner posterior margin deeply concave, forming a broadly rounded posterior projection about the size of 0.5–1 lateral OD (Fig. 87A) (United States west of ~99° and Mexico) 11

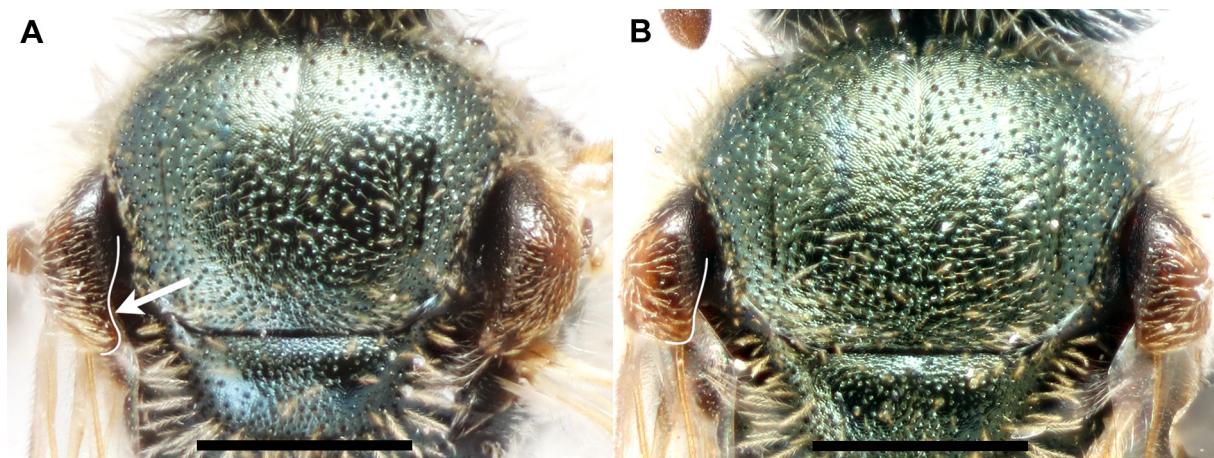

Fig. 87. Tegulae. **A.** *Lasioglossum angelicum* sp. nov., ♀, large with inner posterior margin concave and distinct posterior projection (outline and arrow). **B.** *L. diabolicum* sp. nov., ♀, small with inner posterior margin nearly straight and no posterior projection (outline). Scale bars = 0.5 mm.

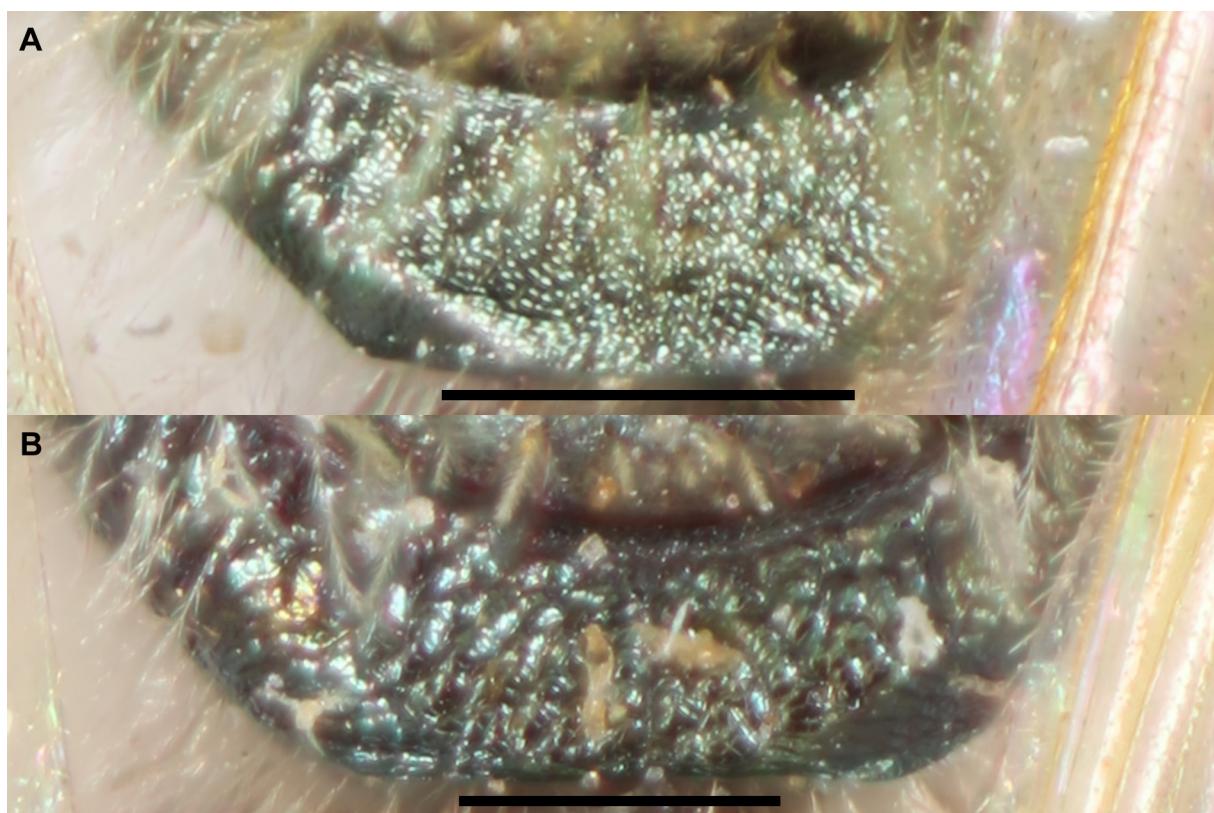

Fig. 88. Metapostnotum. **A.** *Lasioglossum pseudotegulare* (Cockerell, 1896), ♀, completely dull with fine rugae obscured by microsculpture. **B.** *L. tegulariforme* (Crawford, 1907), ♀, shiny with strong rugae. Scale bars = 0.25 mm.

- Tegula relatively small (maximum length about half ITS or less and at most reaching posterior margin of mesoscutum in dorsal view), more sparsely punctate medially (IS ≥ 1 PD), and with inner posterior margin straight or weakly concave, forming a sharp posterior angle or point smaller than 0.5 lateral OD (Fig. 87B) (if tegula larger or more densely punctate, then occurring in United States east of $\sim 99^\circ$) 17
- 11. Metapostnotum smooth with fine, subparallel rugae and completely dull due to fine reticulate microsculpture (Fig. 88A) 12
- Metapostnotum roughened with strong, usually anastomosing rugae (except usually subparallel in *L. gaudiale*) and shiny basally between rugae due to weak microsculpture (Fig. 88B) 13
- 12. Face slightly longer on average (length/width ratio 0.8–0.85) (Fig. 89A); mesepisternum densely punctate (IS < 1 PD) and usually shiny; mesoscutum uniformly dull due to strong tessellate microsculpture; in Nearctic region, T1–T2 apical rims distinctly punctate with no change in sculpture across premarginal line (impunctate in Neotropics) *L. pseudotegulare* (Cockerell, 1896)
- Face slightly shorter on average (length/width ratio 0.77–0.84) (Fig. 89B); mesepisternum usually dull or more sparsely punctate (with some IS ≥ 1 PD) and/or mesoscutum shiny at least on lateral and posterior margins; T1–T2 apical rims impunctate or punctures much sparser and finer than on discs *L. stictaspis* species complex [in part]
- 13. T1 disc with impunctate median line 1 OD wide or slightly less (Fig. 90A) *L. tegulariforme* (Crawford, 1907)
 - T1 disc evenly punctate throughout (Fig. 90B) 14
- 14. T1 disc punctures very fine and sparse (IS = 1–4 PD), much sparser than punctures in T2 basal half, or if similar, then all punctures very fine (no wider than fine setae arising from them) and somewhat obscured by coriarious microsculpture on T1–T2 discs (Fig. 91A) *L. stictaspis* species complex [in part]
- T1 disc punctures distinct and moderately dense (IS = 1–2 PD), similar to punctures in T2 basal half; T1–T2 shiny except sometimes coriarious on T1 anterior slope or T2 apical rim (Fig. 91B) 15

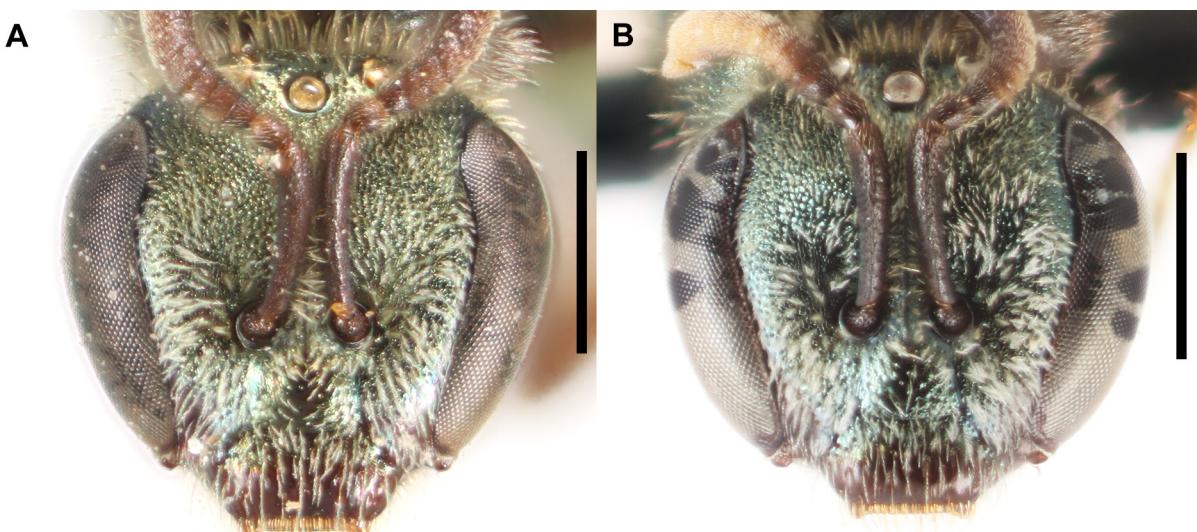

Fig. 89. Face. A. *Lasioglossum pseudotegulare* (Cockerell, 1896), ♀, slightly longer. B. *L. stictaspis* (Sandhouse, 1923), ♀, slightly shorter. Scale bars = 0.5 mm.

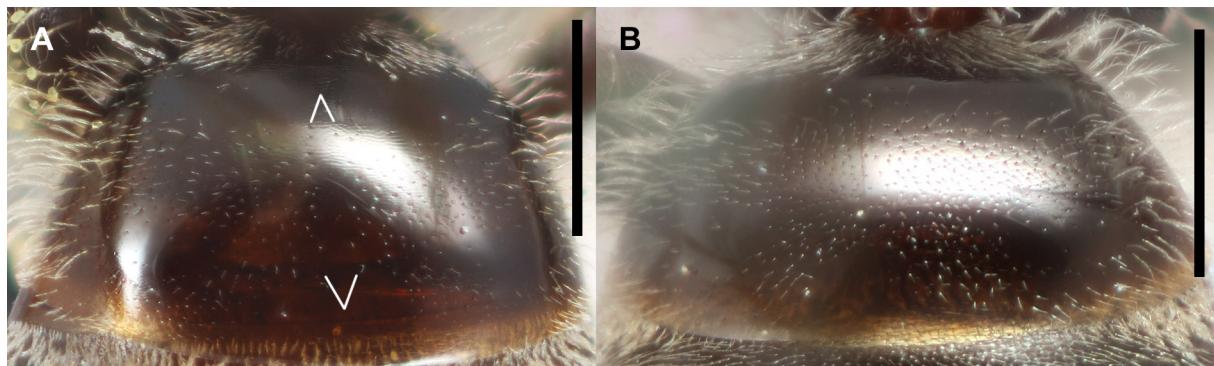

Fig. 90. T1 disc. **A.** *Lasioglossum tegulariforme* (Crawford, 1907), ♀, with median impunctate line about 1 OD wide (brackets). **B.** *L. angelicum* sp. nov., ♀, uniformly punctate. Scale bars = 0.5 mm.

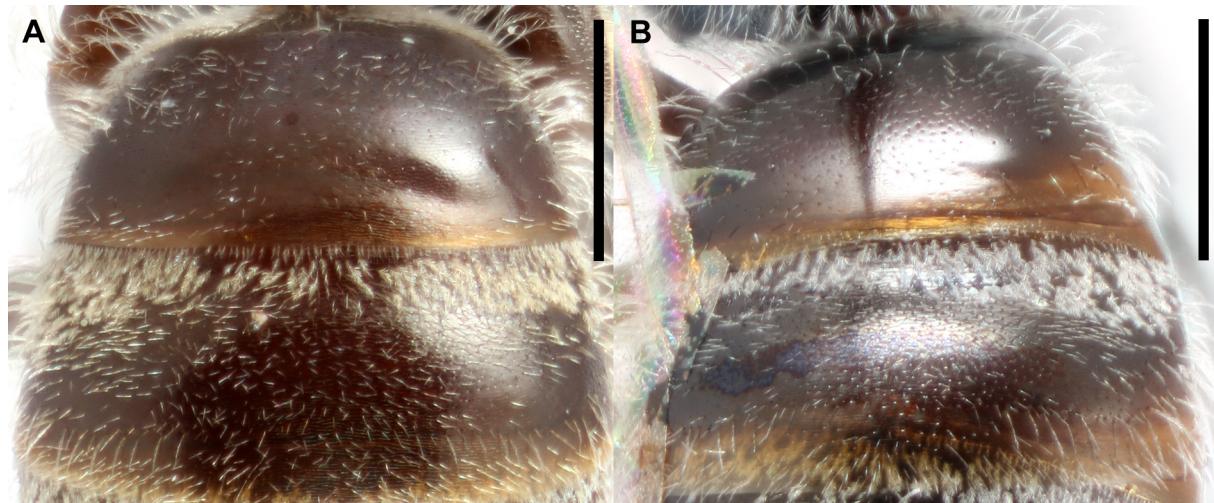

Fig. 91. T1–T2. **A.** *Lasioglossum stictaspis* (Sandhouse, 1923), ♀, dull and finely, somewhat obscurely punctate. **B.** *L. gaudiale* (Sandhouse, 1924), ♀, shiny and deeply, distinctly punctate. Scale bars = 0.5 mm.

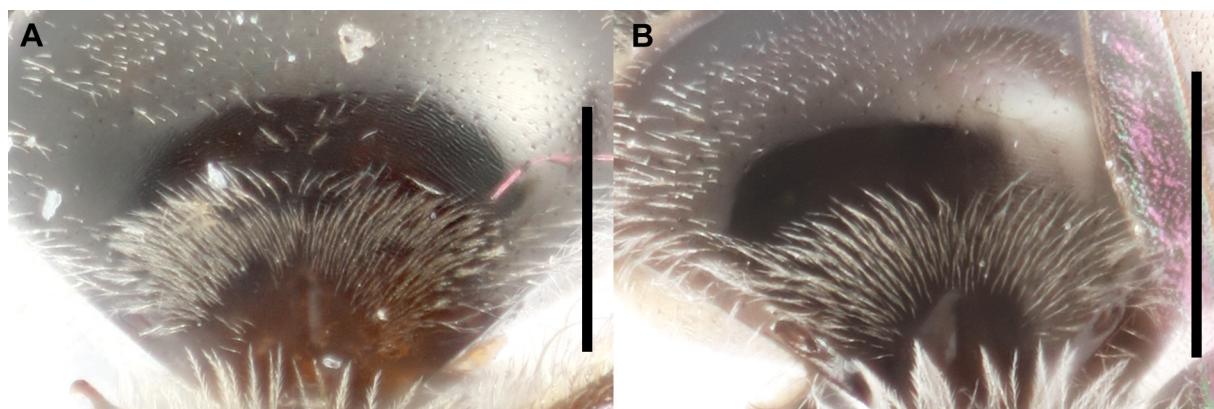

Fig. 92. T1 anterior slope. **A.** *Lasioglossum puteulanum* Gibbs, 2009, ♀, coriarious. **B.** *L. angelicum* sp. nov., ♀, smooth and shiny. Scale bars = 0.5 mm.

15. T1 anterior slope usually dulled by strong coriarious microsculpture (as in Fig. 92A); mesoscutum very densely and finely punctate (posterior half with no IS > 1 PD and 4–5 punctures present between posterior end of parapsidal line and lateral edge of mesoscutum) (as in Fig. 93A); T3 usually with sparse tomentum throughout disc *L. helianthi* (Cockerell, 1916) [in part]
- T1 anterior slope shiny, mirror-smooth, with at most weak microsculpture not dulling surface (Fig. 92B); mesoscutum more sparsely or coarsely punctate (posterior half with IS = 1–3 PD in centre or only 2–3 punctures present between posterior end of parapsidal line and lateral edge of mesoscutum, except sometimes in *L. angelicum* sp. nov.) (Fig. 93B); T3 with tomentum limited to basal band and, at most, a thin, sparse subapical band which is broadly interrupted medially 16

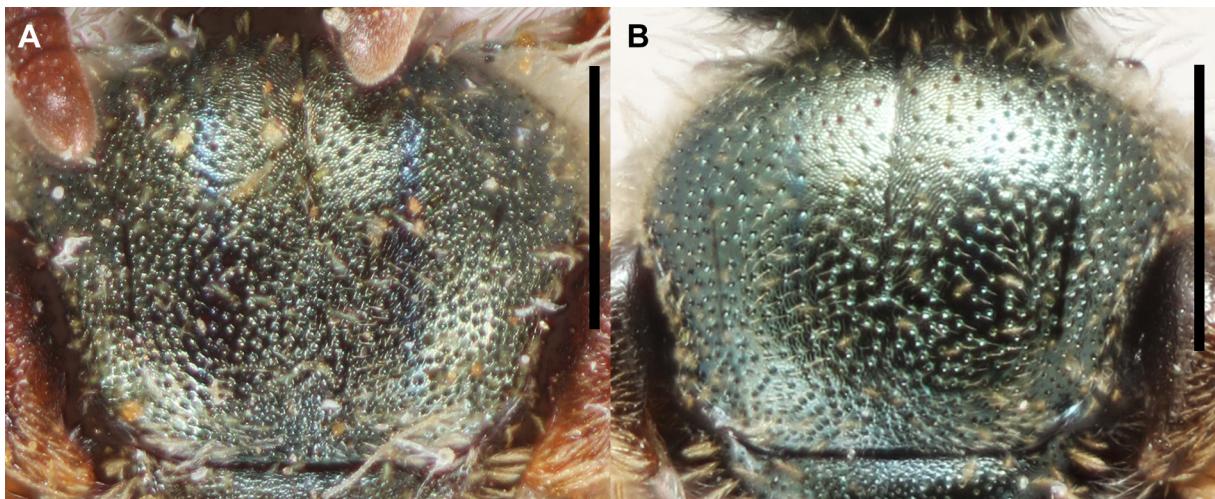

Fig. 93. Mesoscutum. **A.** *Lasioglossum tegulariforme* (Crawford, 1907), ♀, finely and very densely punctate. **B.** *L. angelicum* sp. nov., ♀, coarsely and moderately sparsely punctate. Scale bars = 0.5 mm.

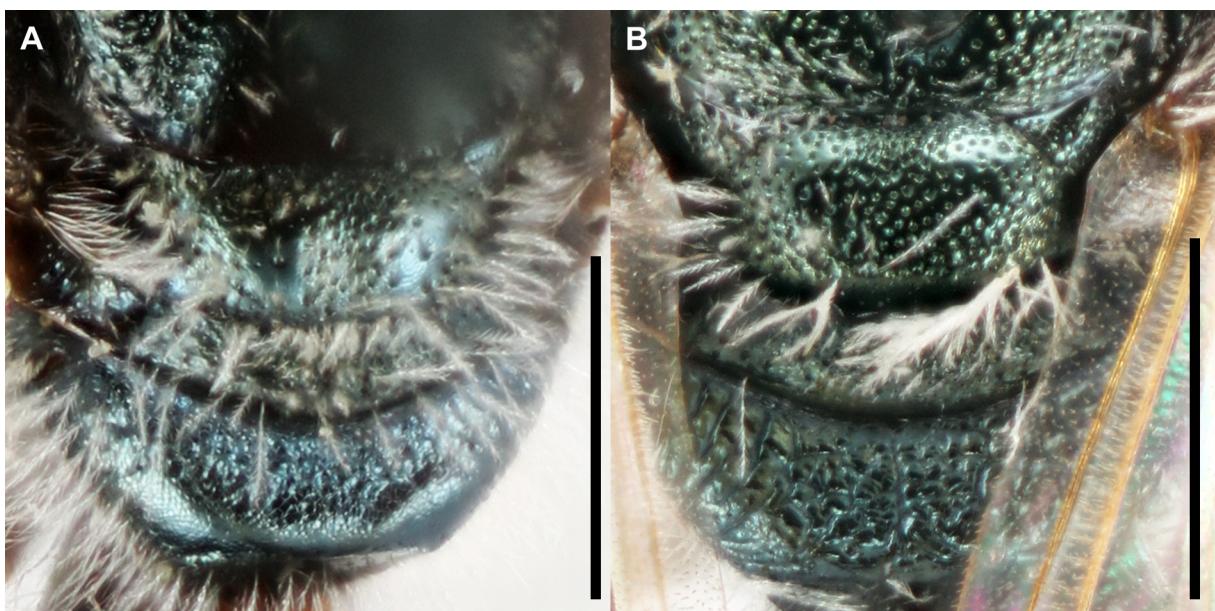

Fig. 94. Scutellum and metapostnotum. **A.** *Lasioglossum gaudiale* (Sandhouse, 1924), ♀, scutellum coarsely punctate and metapostnotum rugae not reaching posterior margin. **B.** *L. eremum* sp. nov., ♀, scutellum finely punctate and metapostnotum rugae reaching posterior margin. Scale bars = 0.5 mm.

16. Gena about as wide as eye in lateral view; metapostnotum rugae usually subparallel and not reaching posterior margin (Fig. 94A); scutellum often very coarsely and sparsely punctate in comparison to mesoscutum posterior margin ($IS = 1–2 PD$) (Fig. 94A) *L. gaudiale* (Sandhouse, 1924) [in part]
- Gena narrower than eye in lateral view; metapostnotum rugae usually anastomosing and reaching posterior margin (as in Fig. 94B); scutellum finely and densely punctate ($IS < 1 PD$ except sometimes submedially), similar to mesoscutum posterior margin (as in Fig. 94B) *L. angelicum* sp. nov.
17. Tegula inner posterior margin straight or nearly so and clearly not reaching posterior margin of mesoscutum in dorsal view (Fig. 95A) 18
- Tegula inner posterior margin concave or sinuous and reaching posterior margin of mesoscutum in dorsal view (Fig. 95B) 21
18. Frons above frontal carina dull, reticulate, with no distinct interspaces between punctures (Fig. 96A) (United States west of Rocky Mountains and Mexico) 19
- Frons above frontal carina shiny due to narrow interspaces between punctures (Fig. 96B) (Florida and Bahamas) 20

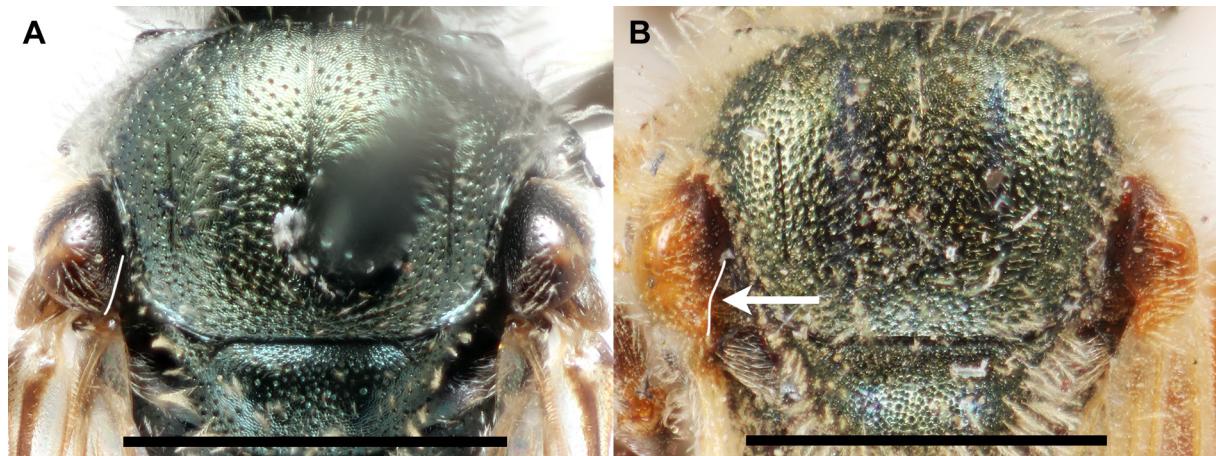

Fig. 95. Tegulae. A. *Lasioglossum holzenthalii* sp. nov., ♀, not reaching posterior margin of mesoscutum and inner posterior margin straight (outline on left). B. *L. ellisiae* (Sandhouse, 1924), ♀, reaching posterior margin of mesoscutum and inner posterior margin concave (arrow and outline on left). Scale bars = 1 mm.

Fig. 96. Frons. A. *Lasioglossum holzenthalii* sp. nov., ♀, roughened and dulled by crowded punctures without distinct interspaces. B. *L. lepidii* (Graenicher, 1927), ♀, smooth and shiny between punctures. Scale bars = 0.5 mm.

19. T1–T3 apical rims usually deeply and distinctly punctate, similar to discs (Fig. 97A); postgena anterior half smooth, shiny or imbricate (as in Fig. 82A); T2–3 with sparse basal bands of tomentum not obscuring the surface underneath and much narrower medially than laterally (Fig. 97A)
L. holzenthalii sp. nov.
- T1–T3 apical rims impunctate (Fig. 97B); postgena anterior half lineate (as in Fig. 82B); T2–3 with dense basal bands of tomentum obscuring the surface underneath and about as wide medially as laterally (Fig. 97B)
L. diabolicum sp. nov. [in part]

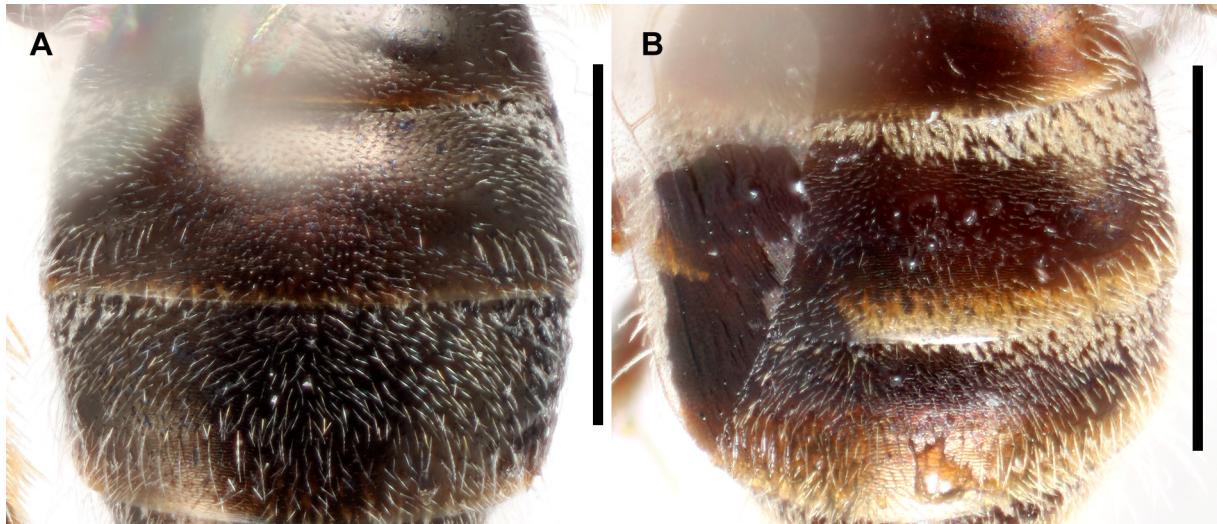

Fig. 97. T1–T3. **A.** *Lasioglossum holzenthalii* sp. nov., ♀, with thin, sparse basal bands of tomentum and apical rims deeply and distinctly punctate. **B.** *L. diabolicum* sp. nov., ♀, with thick, dense basal bands of tomentum and apical rims impunctate. Scale bars = 1 mm.

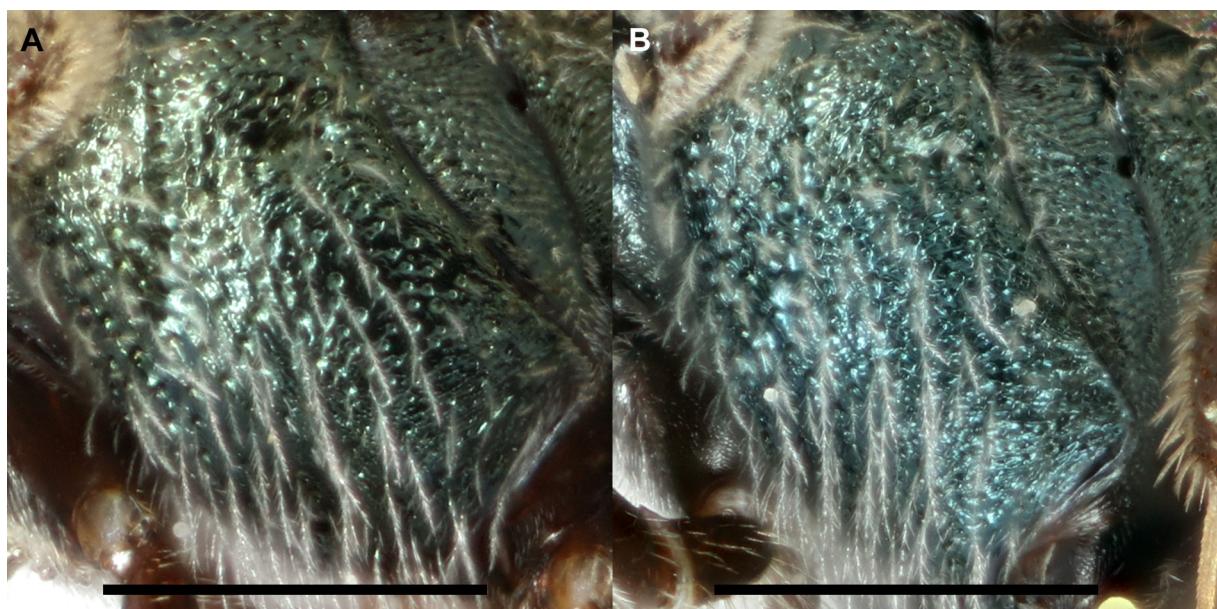

Fig. 98. Mesepisternum. **A.** *Lasioglossum diabolicum* sp. nov., ♀, shiny with distinct round punctures. **B.** *L. tegulare* (Robertson, 1890), ♀, dull and rugulose. Scale bars = 0.5 mm.

- 20. Tegula and metasoma dark brown to black *L. lepidii* (Graenicher, 1927)
 - Tegula and metasoma reddish brown to orange *L. surianae* (Mitchell, 1960) [in part]
- 21. Mesepisternum with distinct round punctures; surface often shiny (Fig. 98A) 22
 - Mesepisternum punctures either indistinct or so crowded (IS = 0 PD) that most are polygonal, not round; surface dull, imbricate or rugulose (Fig. 98B) 27
- 22. T1 disc punctures very fine and sparse (IS = 1–4 PD), much sparser than punctures in T2 basal half, or if similar, then all punctures very fine (no wider than fine setae arising from them) and somewhat obscured by coriaceous microsculpture on T1–T2 discs (Fig. 91A) 23
 - T1 disc punctures distinct and moderately dense (IS = 1–2 PD), similar to punctures in T2 basal half; T1–T2 discs shiny or with microsculpture not obscuring the punctures (Fig. 91B) 25
- 23. Mesepisternum punctures similar in size and density to those of hypoepimeron (Fig. 99A); tegula sparsely punctate medially (IS = 1–3 PD); metapostnotum roughened with strong rugae and shiny basally between rugae due to weak microsculpture (as in Fig. 88B) (east of Rocky Mountains) *L. ellisiae* (Sandhouse, 1924) [in part]
 - Mesepisternum punctures slightly larger and sparser than those of hypoepimeron (Fig. 99B), or if similar, then occurring west of Rocky Mountains; tegula often densely punctate medially (IS ≤ 1 PD); metapostnotum often smooth with fine rugae and completely dull due to fine reticulate microsculpture (as in Fig. 88A) 24
- 24. Tegula with a blunt angle posteriorly (outline and arrow, Fig. 100A) and usually sparsely punctate medially (IS = 1–3 PD) *L. diabolicum* sp. nov. [in part]
 - Tegula with at least a small rounded posterior projection (outline and arrow, Fig. 100B) and usually densely punctate medially (IS ≤ 1 PD) *L. stictaspis* species complex [in part]

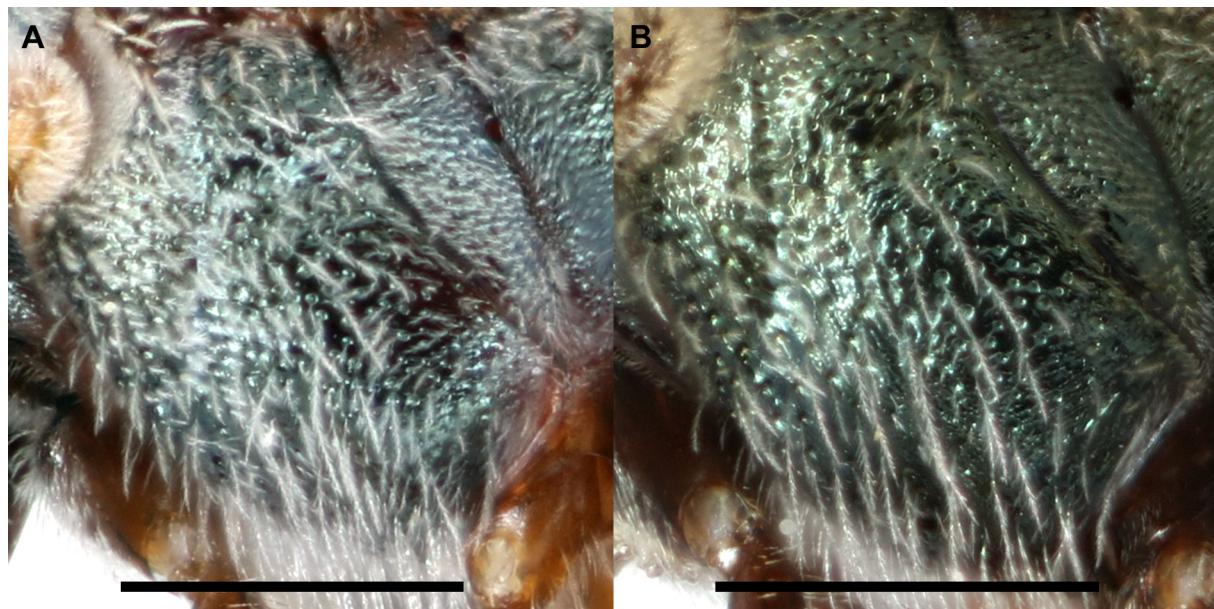

Fig. 99. Mesepisternum. **A.** *Lasioglossum ellisiae* (Sandhouse, 1924), ♀, punctures similar to hypoepimeron. **B.** *L. diabolicum* sp. nov., ♀, punctures slightly larger and coarser than on hypoepimeron. Scale bars = 0.5 mm.

25. Mesoscutum finely and densely punctate (4–5 punctures present between posterior end of parapsidal line and lateral edge of mesoscutum, separated by <0.5 PD) (as in Fig. 93A); T3 usually with sparse tomentum throughout disc *L. helianthi* (Cockerell, 1916) [in part]
- Mesoscutum coarsely punctate (2–3 punctures present between posterior end of parapsidal line and lateral edge of mesoscutum, which *may* be separated by up to 1 PD) (as in Fig. 93B); T3 with tomentum limited to basal band and, at most, a thin, sparse subapical band which is broadly interrupted medially 26
26. T1 anterior slope shiny, mirror-smooth, with at most weak microsculpture not dulling surface (as in Fig. 92B); scutellum often sparsely punctate in comparison to mesoscutum posterior margin (IS = 1–2 PD) (Fig. 94A); metapostnotum rugae usually not reaching posterior margin or extending onto propodeum dorsolateral slope except at extreme base (Fig. 94A) *L. gaudiale* (Sandhouse, 1924) [in part]
- T1 anterior slope dulled by coriarious microsculpture (as in Fig. 92A); scutellum densely punctate (IS < 1 PD), similar to mesoscutum posterior margin (Fig. 94B); metapostnotum rugae reaching posterior margin and extending onto most of propodeum dorsolateral slope (Fig. 94B) *L. eremum* sp. nov.
27. T2–3 with dense basal bands of tomentum obscuring the surface underneath and about as wide medially as laterally (Fig. 97B) (west of Rocky Mountains, except Hawaii) *L. diabolicum* sp. nov. [in part]
- T2–3 with sparse basal bands of tomentum not obscuring the surface underneath and much narrower medially than laterally (as in Fig. 97A) (east of Rocky Mountains and Hawaii) 28
28. Face slightly longer on average (length/width ratio 0.81–0.87) (Fig. 101A); tegula slightly more sparsely punctate medially (IS = 1–2 PD); head and mesosoma usually blue to blue-green (southeastern United States and Hawaii) *L. puteulanum* Gibbs, 2009
- Face slightly shorter on average (length/width ratio 0.8–0.85) (Fig. 101B); tegula slightly more densely punctate medially (IS ≤ 1 PD); head and mesosoma usually olive green (eastern United States) 29
29. Inner hind tibial spur with 3 or 4 subapical teeth *L. tegulare* (Robertson, 1890)
- Inner hind tibial spur with 2 subapical teeth *L. carlinvillense* Gibbs, 2009

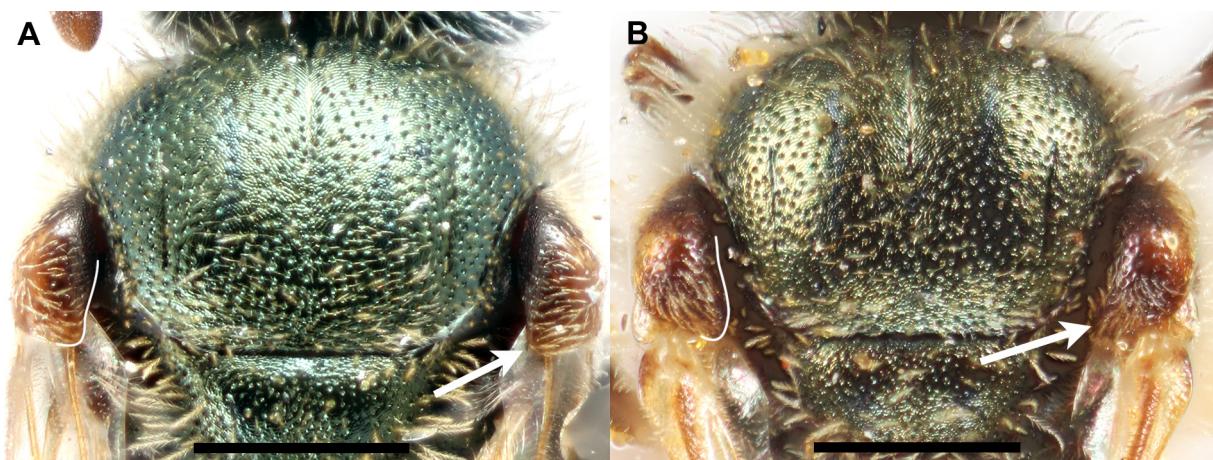

Fig. 100. Tegulae. **A.** *Lasioglossum diabolicum* sp. nov., ♀, with blunt posterior angle (white outline and arrow). **B.** *L. stictaspis* (Sandhouse, 1923), ♀, with rounded posterior projection (white outline and arrow). Scale bars = 0.5 mm.

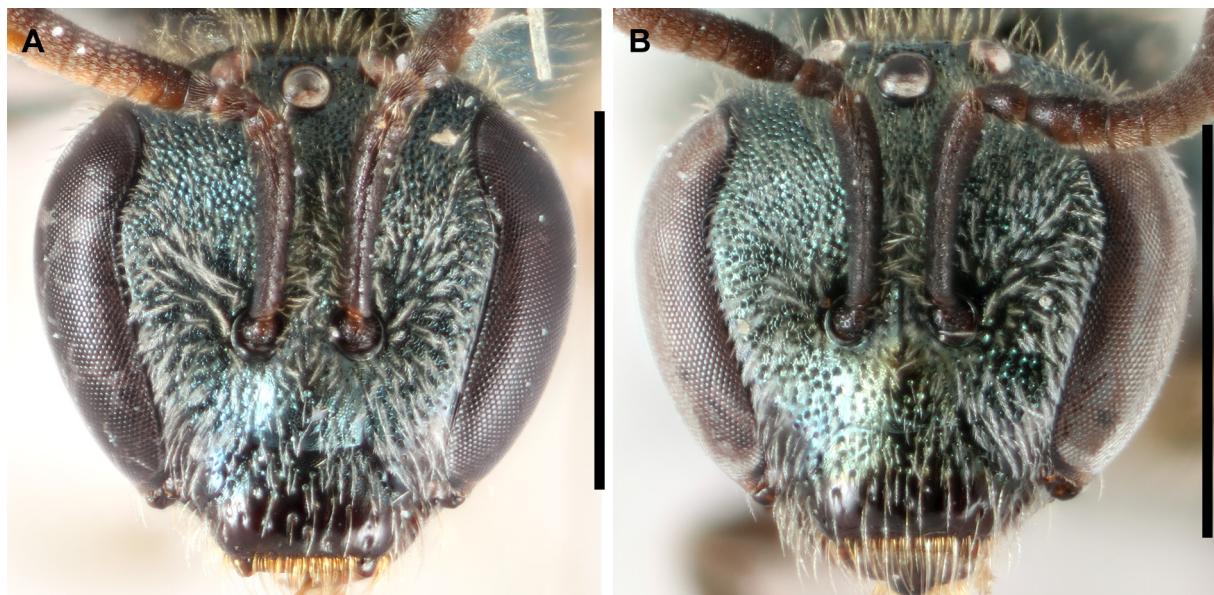

Fig. 101. Face. **A.** *Lasioglossum puteulanum* Gibbs, 2009, ♀, slightly longer. **B.** *L. tegulare* (Robertson, 1890), ♀, slightly shorter. Scale bars = 1 mm.

Key to males

1. Tegula impunctate except on extreme anterior margin (as in Fig. 81A); face uniformly covered in dense tomentum at least below eye emargination (Fig. 102B–D) 2
- Tegula with at least a few distinct punctures medially, usually many (as in Fig. 81B–C), or (rarely) if impunctate, then face with dense tomentum limited to paraocular area (Fig. 102A) 4
2. Mesoscutum tessellate anteriorly and often posteriorly; face with dense appressed tomentum at level of eye emargination and below (as in Fig. 102B) (eastern Texas, Nuevo Leon, and Tamaulipas) *L. rufodeludens* sp. nov.
- Mesoscutum shiny, at most weakly tessellate anteromedially; face with dense appressed tomentum slightly above level of eye emargination (Fig. 102C) (Chihuahuan and Sonoran deserts) 3

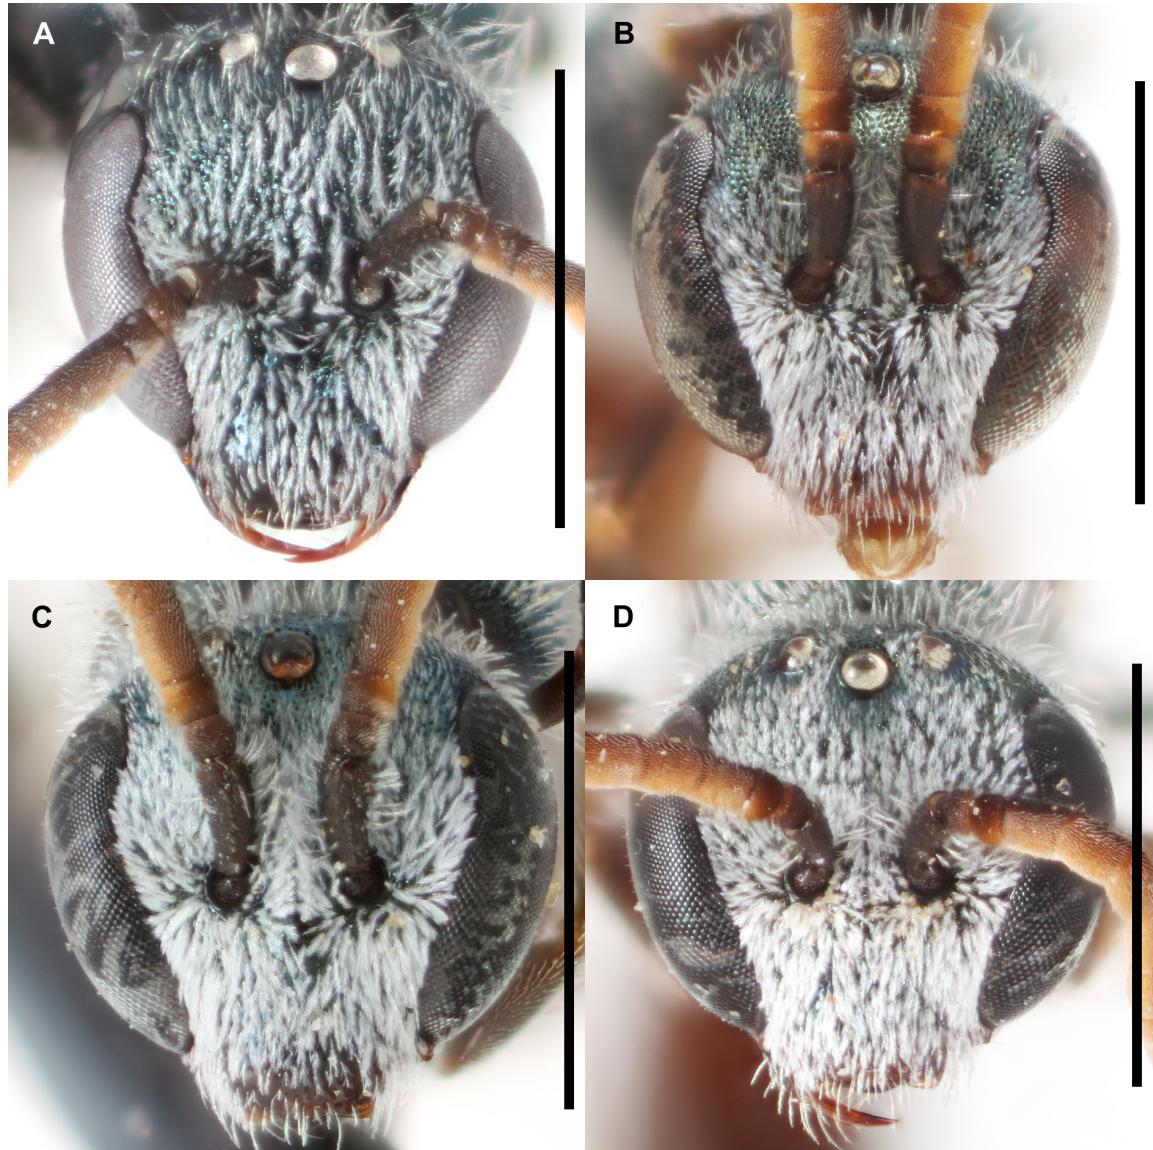

Fig. 102. Face. **A.** *Lasioglossum holzenthalii* sp. nov., ♂, with dense tomentum on lower paraocular areas and sparser tomentum between. **B.** *L. ellisiae* (Sandhouse, 1924), ♂, with dense tomentum below eye emargination. **C.** *L. deludens* sp. nov., ♂, with dense tomentum slightly above eye emargination. **D.** *L. gloriosum* sp. nov., ♂, with dense tomentum below ocelli. Scale bars = 1 mm.

- 3. Tegula yellow-orange (Chihuahuan and Sonoran deserts) *L. deludens* sp. nov.
- Tegula dark brown (Chihuahuan desert) *L. profundum* sp. nov.

- 4. Face covered in dense appressed tomentum up to median ocellus or nearly so (Fig. 102D); mesoscutum often fringed with tomentum (as in Fig. 83A) 5
- Face covered in dense appressed tomentum only up to eye emargination (Fig. 102B) or tomentum restricted to lower paraocular area (Fig. 102A); mesoscutum without tomentum (as in Fig. 83B) ...
- 7

- 5. Preepisternum and metepisternum with sparse tomentum not obscuring the surface underneath (Fig. 103A); face usually narrower (length/width ratio > 0.83) (Fig. 104A) *L. gaudiale* (Sandhouse, 1924)
- Preepisternum and metepisternum with dense tomentum largely obscuring the surface underneath (Fig. 103B); face broad (length/width ratio ≤ 0.83) (Fig. 104B) 6

- 6. Mesoscutum mostly densely punctate ($IS < 1$ PD); tegula inner posterior margin strongly concave and rugulose; metapostnotum rugae usually reaching posterior margin; head and mesosoma integument mostly olive green (north of $\sim 34^\circ$) (Fig. 105A) *L. gloriosum* sp. nov.
- Mesoscutum mostly moderately sparsely punctate ($IS = 1–2$ PD); tegula inner posterior margin weakly concave and distinctly punctate; metapostnotum rugae usually not reaching posterior margin; head and mesosoma integument mostly blue (south of $\sim 34^\circ$) (Fig. 105B) *L. indagator* sp. nov.

- 7. T1–T4 each strongly convex in lateral view (Fig. 106A); apical rim abruptly depressed and impunctate, contrasting with densely punctate discs along premarginal line ($IS < 1$ PD) (Fig. 107A) *L. coactus* (Cresson, 1872)
- T1–T4 each mostly flat in lateral view (Fig. 106B); apical rim slightly depressed, with more gradual change or no change in sculpture across premarginal line (Fig. 107B) 8

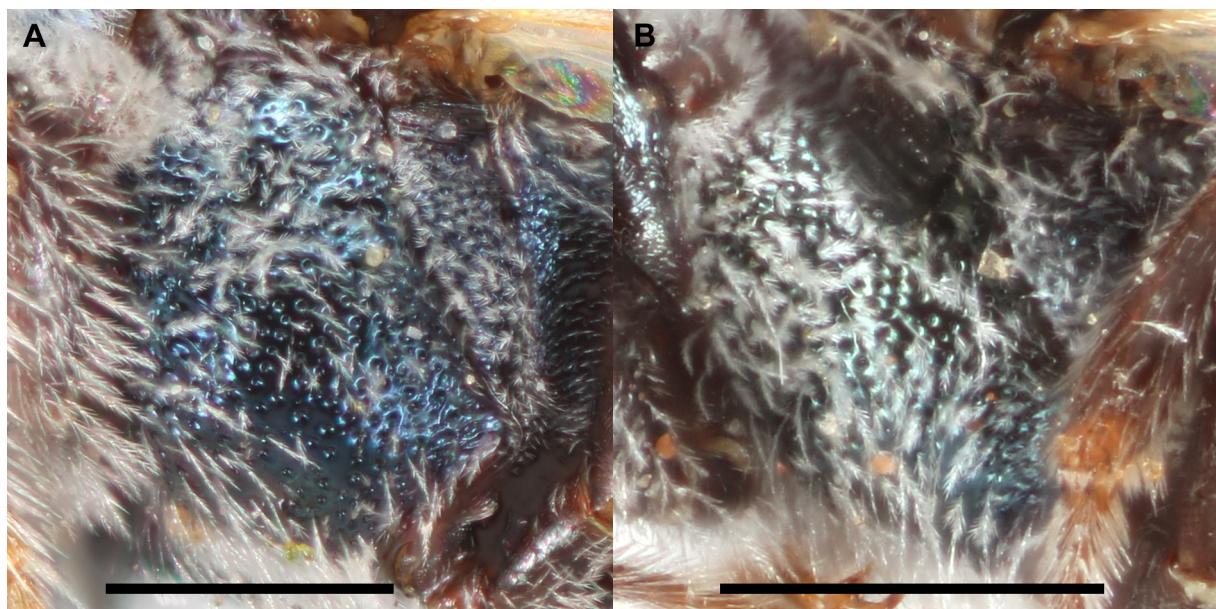

Fig. 103. Pleura. **A.** *Lasioglossum gaudiale* (Sandhouse, 1924), ♂, with sparse tomentum not obscuring the surface. **B.** *L. gloriosum* sp. nov., ♂, with dense tomentum obscuring the surface on preepisternum and metepisternum. Scale bars = 0.5 mm.

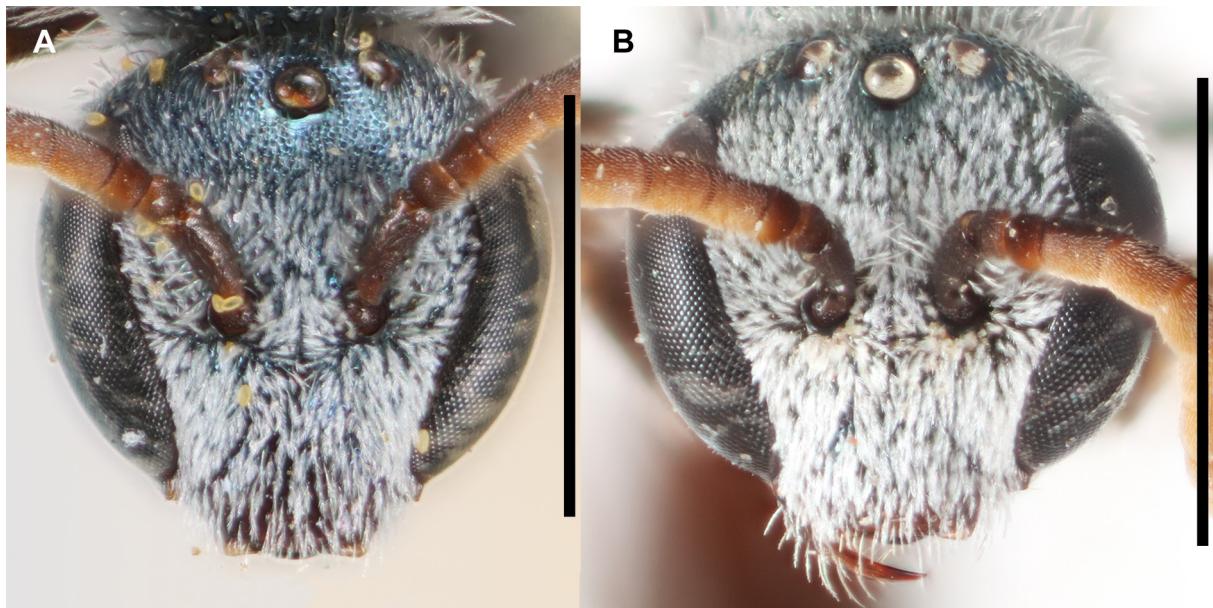

Fig. 104. Face. **A.** *Lasioglossum gaudiale* (Sandhouse, 1924), ♂, slightly narrower. **B.** *L. gloriosum* sp. nov., ♂, broad. Scale bars = 1 mm.

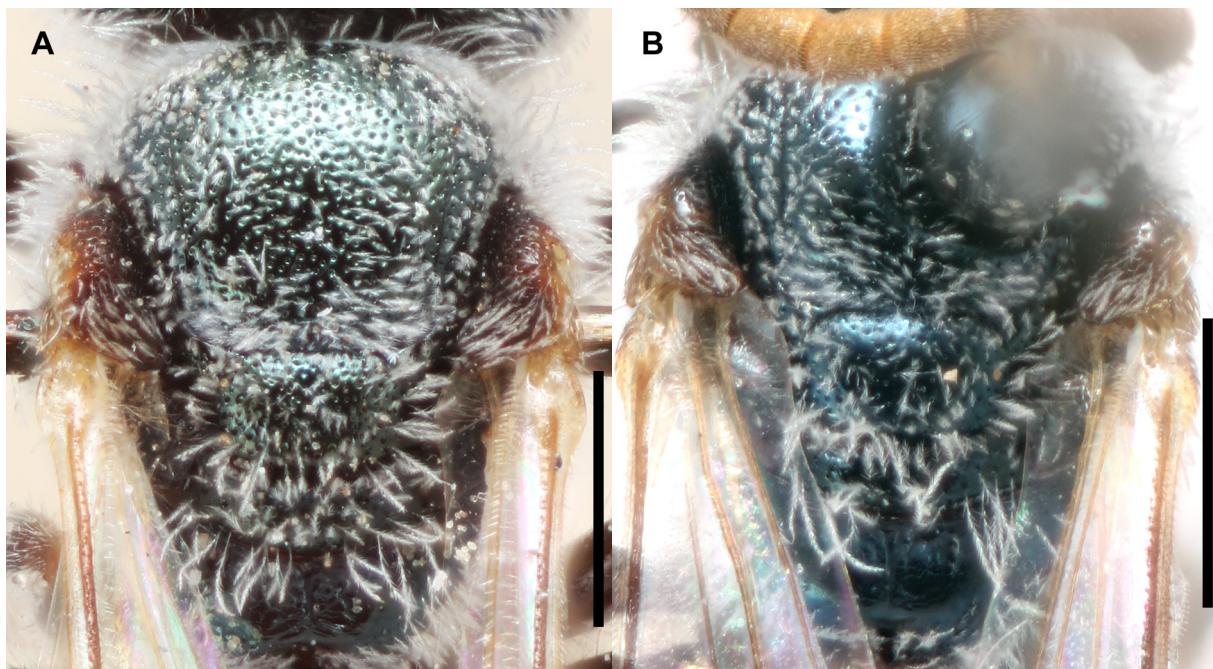

Fig. 105. Mesonotum. **A.** *Lasioglossum gloriosum* sp. nov., ♂, with mesoscutum densely punctate, tegula inner posterior margin strongly concave with crowded punctures, and metapostnotum rugae reaching posterior margin. **B.** *L. indagator* sp. nov., ♂, with mesoscutum sparsely punctate, tegula inner posterior margin weakly concave and more sparsely punctate, and metapostnotum rugae not reaching posterior margin. Scale bars = 0.5 mm.

8. Tegula inner posterior margin deeply concave, with a broadly rounded posterior projection about the size of 0.5–1 lateral OD directed toward axilla and sometimes partially covering it; tegula relatively large (reaching or exceeding posterior margin of mesoscutum in dorsal view) and densely punctate throughout (IS < 1 PD) (as in Fig. 87A) 9
- Tegula inner posterior margin weakly concave or straight, with a blunt posterior angle or point narrower than 0.5 lateral OD and not reaching axilla; tegula relatively small (at most reaching posterior margin of mesoscutum in dorsal view) and often more sparsely punctate medially (IS ≥ 1 PD) (as in Fig. 87B) 17

Fig. 106. Metasomal terga. **A.** *Lasioglossum coactus* (Cresson, 1872), ♂, T1–T3 each strongly convex with abruptly depressed apical rim. **B.** *L. helianthi* (Cockerell, 1916), ♂, T1–T3 each weakly convex with apical rim weakly depressed. Scale bars = 1 mm.

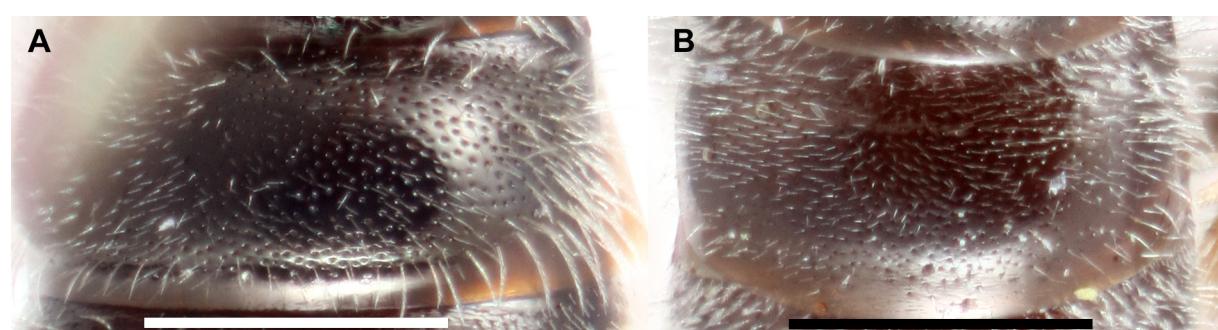

Fig. 107. **A.** *Lasioglossum coactus* Cresson, 1872, ♂, apical rim deeply depressed and impunctate, contrasting with very densely punctate disc. **B.** *L. helianthi* (Cockerell, 1916), ♂, apical rim flat with gradual change in punctuation across premarginal line. Scale bars = 0.5 mm.

- 9. Mesoscutum entirely densely punctate (IS < 1 PD; sometimes with a few scattered IS = 1 PD submedially) (Fig. 108A) (Cascadia bioregion, California, and Hawaii) 10
- Mesoscutum more sparsely punctate (most IS ≥ 1 PD) (Fig. 108B) (not occurring in Cascadia bioregion or Hawaii) 12

- 10. T1 disc punctures slightly but distinctly sparser medially (IS = 1–3 PD) than those of T2 (IS = 1–2 PD); T1–T2 apical rims impunctate except for a few scattered punctures below T1 subapicolateral boss (Fig. 109A) *L. tegulariforme* (Crawford, 1907)
- T1–T2 discs nearly identically, moderately densely punctate (IS = 1–2 PD) and with distinct punctures extending across premarginal line onto basal margin of apical rims (Fig. 109B) 11

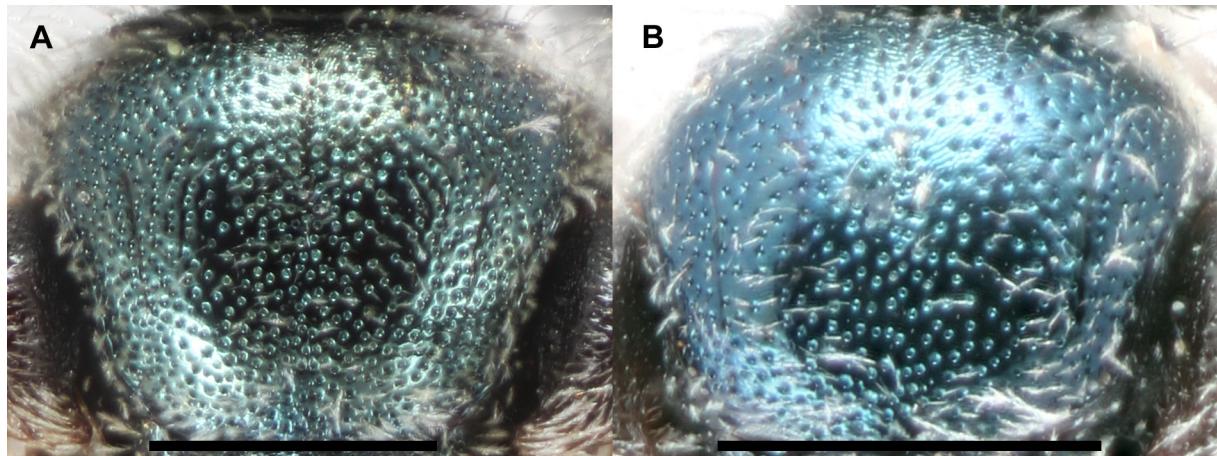

Fig. 108. Mesoscutum. A. *Lasioglossum tegulariforme* (Crawford, 1907), ♂, densely punctate. B. *L. pseudotegulare* (Cockerell, 1896), ♂, moderately sparsely punctate. Scale bars = 0.5 mm.

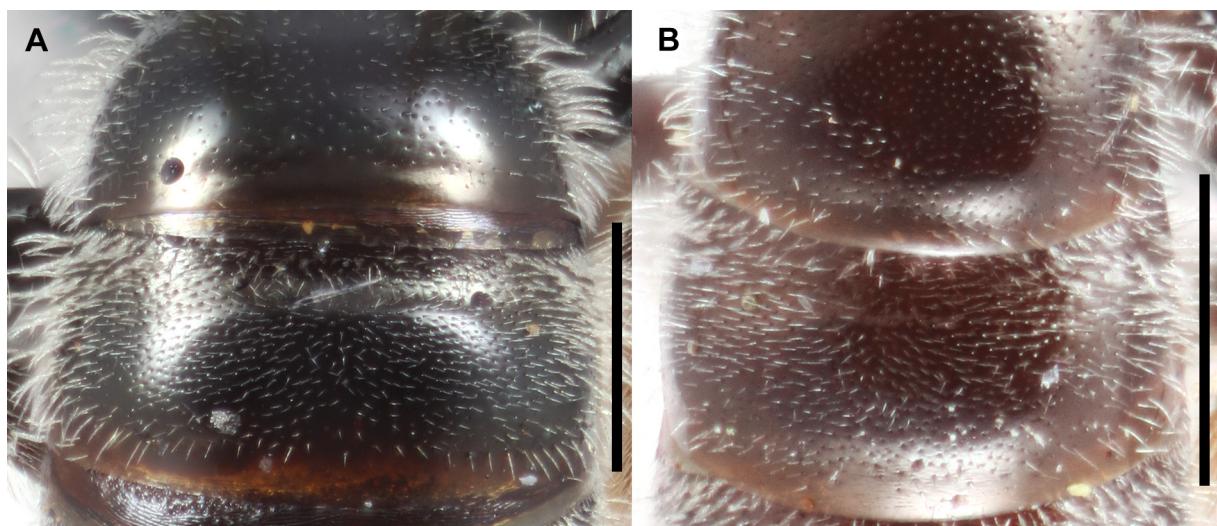

Fig. 109. T1–T2. A. *Lasioglossum tegulariforme* (Crawford, 1907), ♂, T1 more sparsely punctate than T2 and apical rims impunctate. B. *L. helianthi* (Cockerell, 1916), ♂, T1 and T2 uniformly punctate with some punctures on apical rims. Scale bars = 0.5 mm.

- 11. Tegula slightly smaller (maximum length usually $\leq 55\%$ ITS and reaching but not clearly exceeding mesoscutum posterior margin in dorsal view) and with narrower posterior projection closer to the size of 0.5 lateral OD (Fig. 110A) *L. helianthi* (Cockerell, 1916) [in part]
 - Tegula slightly larger (maximum length $> 55\%$ ITS and exceeding mesoscutum posterior margin in dorsal view) and with larger posterior projection closer to the size of 1 lateral OD (Fig. 110B) *L. angelicum* sp. nov. [in part]
12. T1–T2 apical rims with distinct punctures extending across premarginal line onto basal margin of apical rims (Fig. 109B) 13
- T1–T2 apical rims impunctate (except sometimes with a few scattered, minute punctures below T1 subapicolateral boss) (as in Fig. 109A) 15

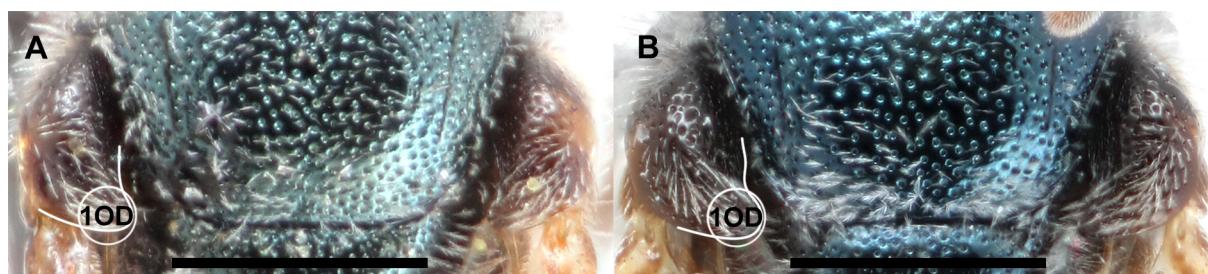

Fig. 110. Tegulae. **A.** *Lasioglossum helianthi* (Cockerell, 1916), ♂, with smaller posterior projection (outline on left) barely exceeding mesoscutum posterior margin. **B.** *L. angelicum* sp. nov., ♂, with larger posterior projection (outline on left) clearly exceeding mesoscutum posterior margin. The white circle corresponds to 1 lateral OD. Scale bars = 0.5 mm.

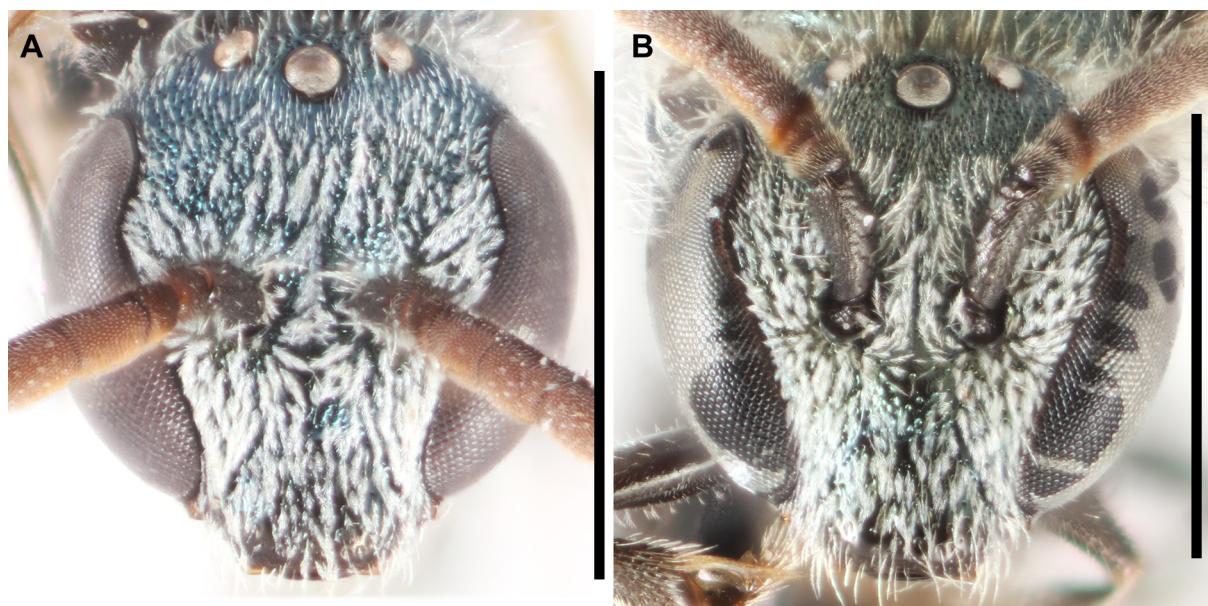

Fig. 111. Face. **A.** *Lasioglossum pseudotegulare* (Cockerell, 1896), ♂, slightly longer. **B.** *L. stictaspis* (Sandhouse, 1923), ♂, slightly shorter. Scale bars = 1 mm.

13. Face slightly longer (length/width ratio usually >0.86) (Fig. 111A); discs of T2–T3 and usually T1 with punctures very dense medially (IS <1 PD), often nearly touching (Fig. 112A) *L. pseudotegulare* (Cockerell, 1896)
- Face slightly shorter (length/width ratio ≤ 0.86) (Fig. 111B); discs of T1–T3 with punctures sparser medially (IS ≥ 1 PD), not close to touching (Fig. 112B) 14
14. Mesepisternum ventral half densely punctate (IS <1 PD); T1 shiny; tarsi and femur-tibia joints dark brown (southern California coast and Los Angeles basin) *L. angelicum* sp. nov. [in part]
- Mesepisternum ventral half more sparsely punctate (IS ≥ 1 PD), T1 coriarious at base, tarsi and femur-tibia joints orange, or occurring in Sonoran Desert and eastward (some specimens are morphologically indistinguishable and can only be separated by geography) *L. stictaspis* species complex [in part]
15. Tegula extremely large (maximum length $>67\%$ ITS and exceeding mesoscutum posterior margin by nearly 1 OD) (Fig. 113A); face slightly longer (length/width ratio usually >0.86) (as in Fig. 111A) (Neotropical Mexico, rarely occurring north to United States border) *L. magnitegula* sp. nov.
- Tegula smaller (maximum length $\leq 67\%$ ITS and exceeding mesoscutum posterior margin by less than 1 OD if at all) (Fig. 113B); face slightly shorter (length/width ratio usually <0.86) (Fig. 111B) 16

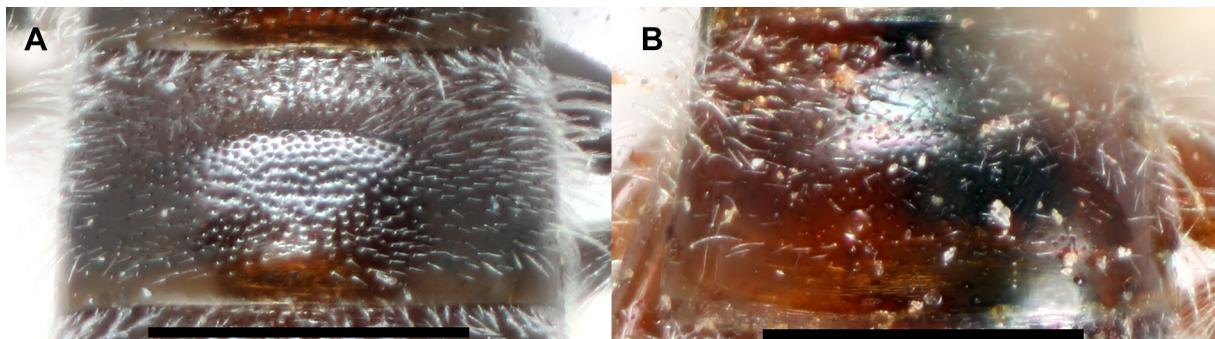

Fig. 112. T2. A. *Lasioglossum pseudotegulare* (Cockerell, 1896), ♂, punctures nearly touching in centre. B. *L. stictaspis* (Sandhouse, 1923), ♂, punctures not close to touching. Scale bars = 0.5 mm.

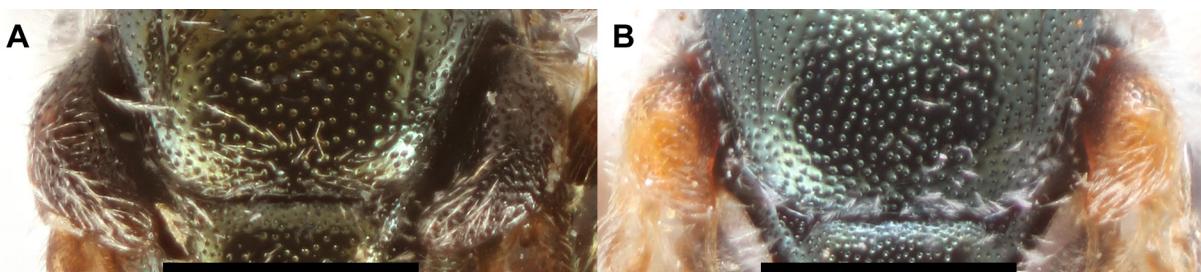

Fig. 113. Tegulae. A. *Lasioglossum magnitegula* sp. nov., ♂, very large and exceeding mesoscutum posterior margin by almost 1 OD. B. *L. ellisiae* (Sandhouse, 1924), ♂, smaller and not exceeding mesoscutum posterior margin. Scale bars = 0.5 mm.

16. Metapostnotum shiny with strong subparallel rugae (as in Fig. 114A) (east of Rocky Mountains to Atlantic coast) *L. ellisiae* (Sandhouse, 1924) [in part]
 – Metapostnotum dulled by strong microsculpture or, if shiny, then rugae anastomosing (Fig. 114B) (west of Rocky Mountains and east to ~102°) *L. stictaspis* species complex [in part]
17. Face with tomentum limited to lower paraocular area and clypeus without tomentum 18
 – Face with uniformly dense tomentum below eye emargination, or if denser in lower paraocular area, then clypeus with some sparse tomentum 19
18. Tegula dark brown with deep, crowded punctures (IS = 0 PD) (high elevations of southwestern United States) *L. eremum* sp. nov.
 – Tegula yellow-orange and very finely and sparsely punctate medially (IS = 2–6 PD) (Florida and Bahamas) *L. surianae* (Mitchell, 1960)
19. T1–T3 apical rims with distinct punctures extending across premarginal line, at least onto basal margin of T1–T2 apical rims (Fig. 109B) 20
 – T1–T3 apical rims impunctate (except sometimes with a few scattered, minute punctures below T1 subapicolateral boss) (as in Fig. 109A) 22
20. Tegula inner posterior margin concave, with a distinct posterior projection longer than 1 mesoscutum PD, and usually densely punctate medially (IS ≤ 1 PD) (Fig. 115A); clypeus usually with tomentum about as dense as on lower paraocular area (as in Fig. 102B) (Cascadia bioregion, Hawaii, and California) *L. helianthi* (Cockerell, 1916) [in part]
 – Tegula inner posterior margin straight or weakly concave, with at most a small posterior bump about 1 mesoscutum PD long, and usually sparsely punctate medially (IS > 1 PD) (Fig. 115B); clypeus usually with tomentum sparser than on lower paraocular area (Fig. 102A) (not occurring in Cascadia bioregion or Hawaii) 21
21. T1–T2 apical rims punctate except T1 apicomediad and far sides of T2 (Fig. 116A); T3 apical rim with at least some punctures; metapostnotum shiny (including posterior margin) *L. holzenthalii* sp. nov.

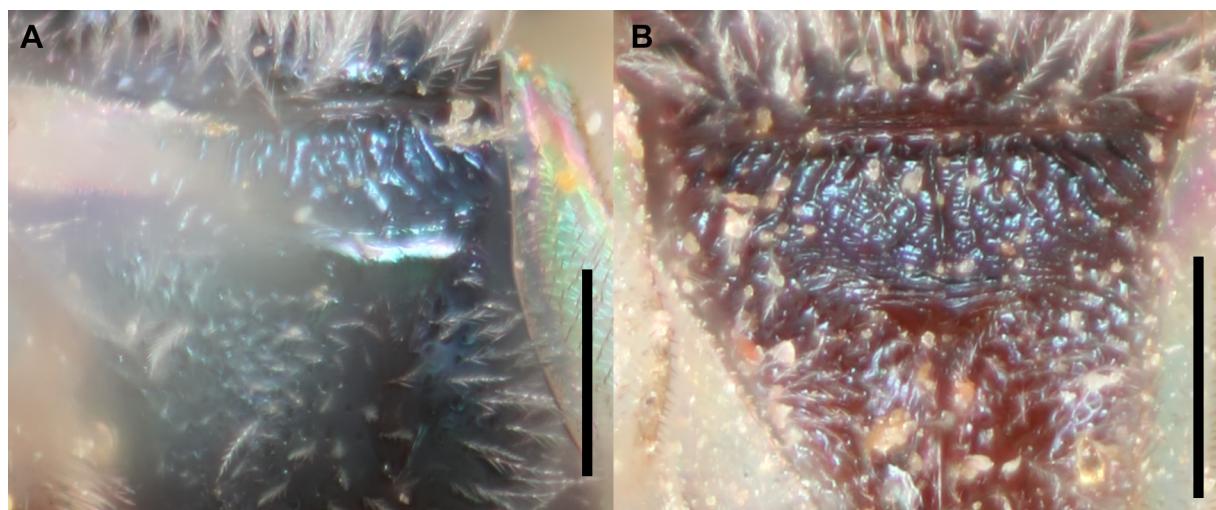

Fig. 114. Metapostnotum. A. *Lasioglossum gaudiale* (Sandhouse, 1924), ♂, shiny with subparallel rugae. B. *L. stictaspis* (Sandhouse, 1923), ♂, dull with anastomosing rugae. Scale bars = 0.25 mm.

- T1–T2 apical rims punctate only on basal margins (Fig. 116B); T3 apical rim impunctate; metapostnotum dulled by strong imbricate microsculpture (most noticeable on posterior margin) *L. perparvum* (Ellis, 1914) [in part]
22. Mesoscutum with sparse erect setae up to 1 OD long, with several gaps half a seta's length wide or wider in lateral view, these setae appearing thin and simple at $40 \times$ magnification (as in Fig. 78A–B) *L. perparvum* (Ellis, 1914) [in part]
- Mesoscutum with dense erect setae 1 OD long or slightly longer, with no gaps half a seta's length wide in lateral view, these setae distinctly plumose at $40 \times$ magnification (as in Fig. 78C–D) 23
23. Discs of T2–T3 uniformly punctate, with dense punctures along premarginal line ($IS \leq 1$ PD), sharply contrasting with impunctate apical rims (Fig. 117A) 24
- Discs of T2–T3 becoming slightly more sparsely punctate near and on premarginal line, without a sharp contrast between discs and apical rims (Fig. 117B) 25

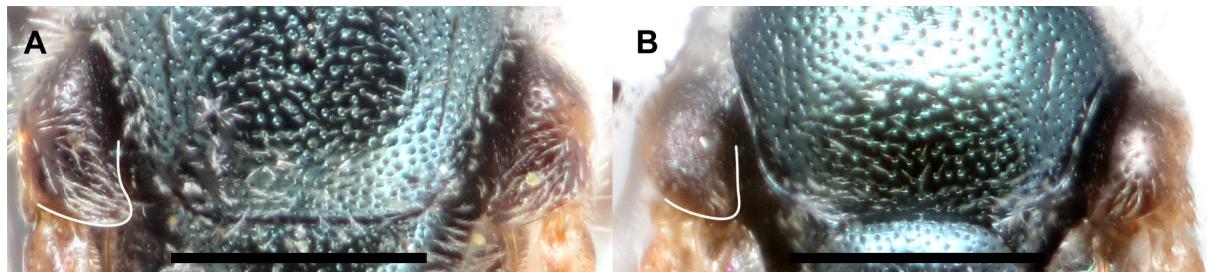

Fig. 115. Tegulae. A. *Lasioglossum helianthi* (Cockerell, 1916), ♂, inner posterior margin concave with distinct posterior projection (outline on left). B. *L. perparvum* (Ellis, 1914), ♂, inner posterior margin nearly straight without posterior projection (outline on left). Scale bars = 0.5 mm.

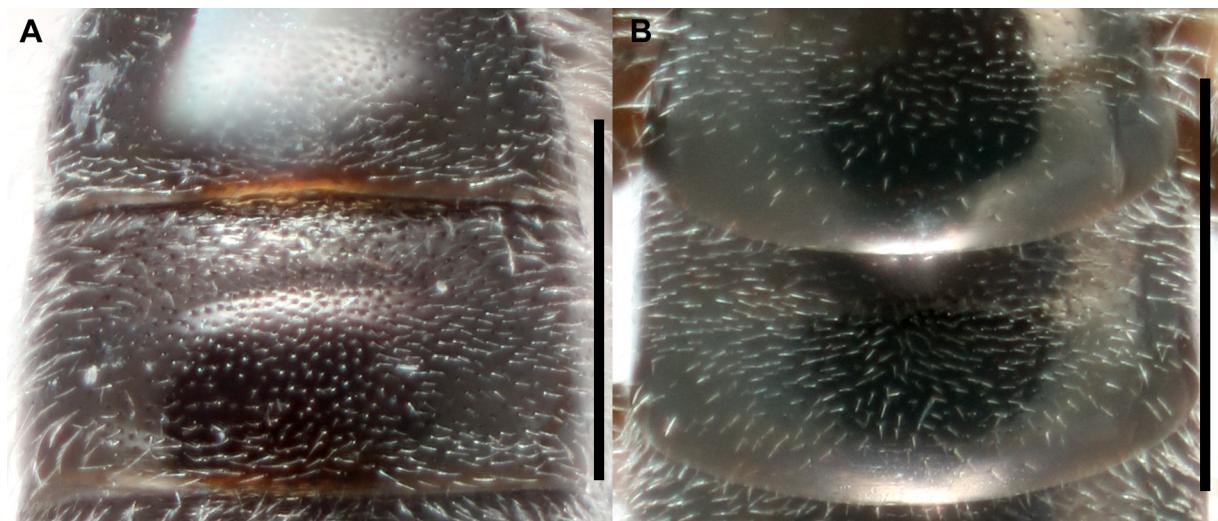

Fig. 116. T1–T2. A. *Lasioglossum holzenthalii* sp. nov., ♂, with apical rims mostly punctate. B. *L. perparvum* (Ellis, 1914), ♂, with apical rims punctate only on basal margin. Scale bars = 0.5 mm.

24. Face slightly longer (length/width ratio ≥ 0.86) (Fig. 118A); tegula slightly more sparsely punctate medially (IS = 1–2 PD); head and mesosoma blue (Hawaii and southeastern United States) *L. puteulanum* Gibbs, 2009
- Face slightly shorter (length/width ratio usually < 0.86) (Fig. 118B); tegula relatively densely punctate medially (IS ≤ 1 PD); head and mesosoma green to bluish (widespread across eastern Canada and United States, excluding Florida) *L. tegulare* (Robertson, 1890)
[*L. carlinvillense* (Gibbs, 2009) may also key here, but male diagnostic characters are not currently known. Small specimens from Illinois to Alabama should be identified with caution, ideally with associated females.]
25. Preepisternum and hypoepimeral area very finely punctate to areolate with punctures smaller than on mesepisternum (Fig. 119A) (Florida) *L. lepidii* (Graenicher, 1927)
- Preepisternum and hypoepimeral area more coarsely punctate to areolate with punctures about the same size as on mesepisternum (Fig. 119B) (not occurring in Florida) 26

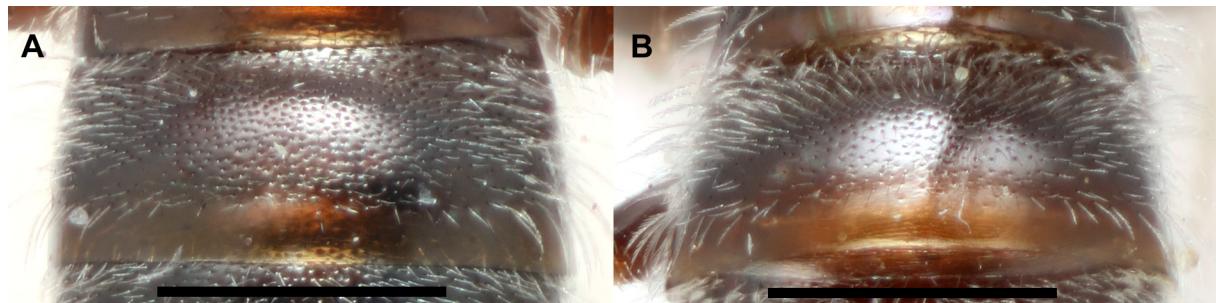

Fig. 117. T2. **A.** *Lasioglossum egulare* (Robertson, 1890), ♂, with dense punctures up to premarginal line sharply contrasting with impunctate apical rim. **B.** *L. diabolicum* sp. nov., ♂, with punctures becoming more sparsely punctate near and on premarginal line and not sharply contrasting with apical rim. Scale bars = 0.5 mm.

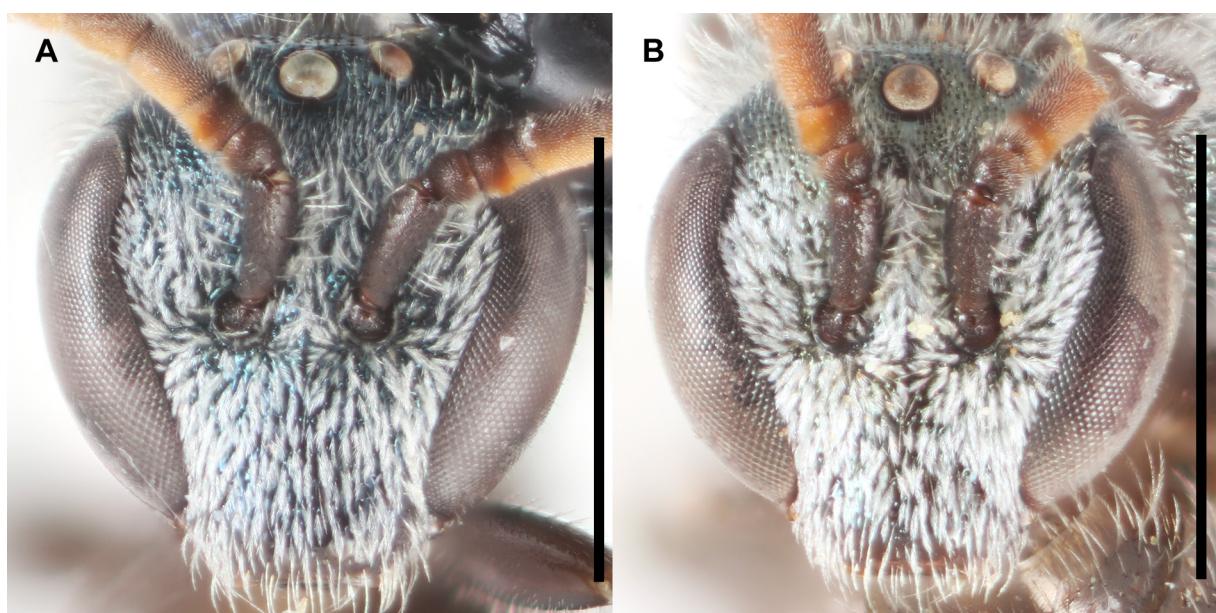

Fig. 118. Face. **A.** *Lasioglossum puteulanum* Gibbs, 2009, ♂, slightly longer. **B.** *L. tegulare* (Robertson, 1890), ♂, slightly shorter. Scale bars = 1 mm.

26. Mesoscutum punctures between parapsidal lines all separated by 1 PD or slightly more or less (Fig. 120A); metapostnotum usually shiny (east of Rocky Mountains) *L. ellisiae* (Sandhouse, 1924) [in part]
 – Mesoscutum between parapsidal lines more irregularly and sparsely punctate, with some IS < 1 PD and some IS ≥ 2 PD (Fig. 120B); metapostnotum usually dulled by strong imbricate microsculpture (west of Rocky Mountains and east to ~102°) 27
27. Tegula relatively small, usually not reaching mesoscutum posterior margin in dorsal view, and inner posterior margin straight or weakly concave, with at most a small posterior bump about 1 mesoscutum PD long (as in Fig. 100A) *L. diabolicum* sp. nov.

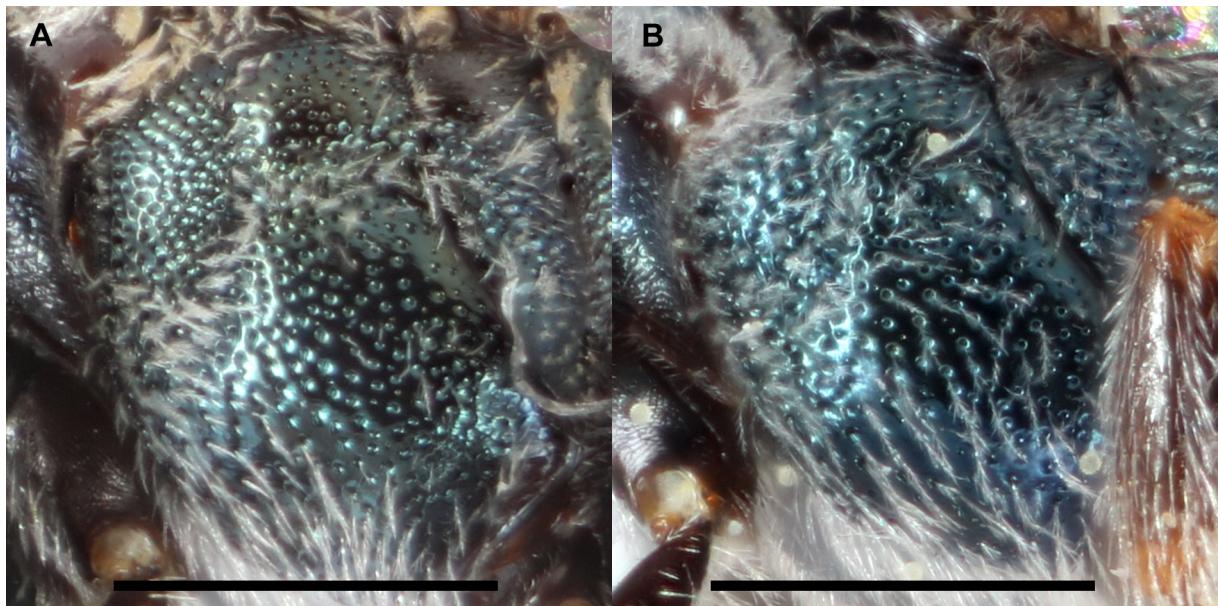

Fig. 119. Pleura. **A.** *Lasioglossum lepidii* (Graenicher, 1927), ♂, preepisternum and hypoepimeron more finely punctate than mesepisternum. **B.** *L. diabolicum* sp. nov., ♂, preepisternum and hypoepimeron as coarsely punctate as mesepisternum. Scale bars = 0.5 mm.

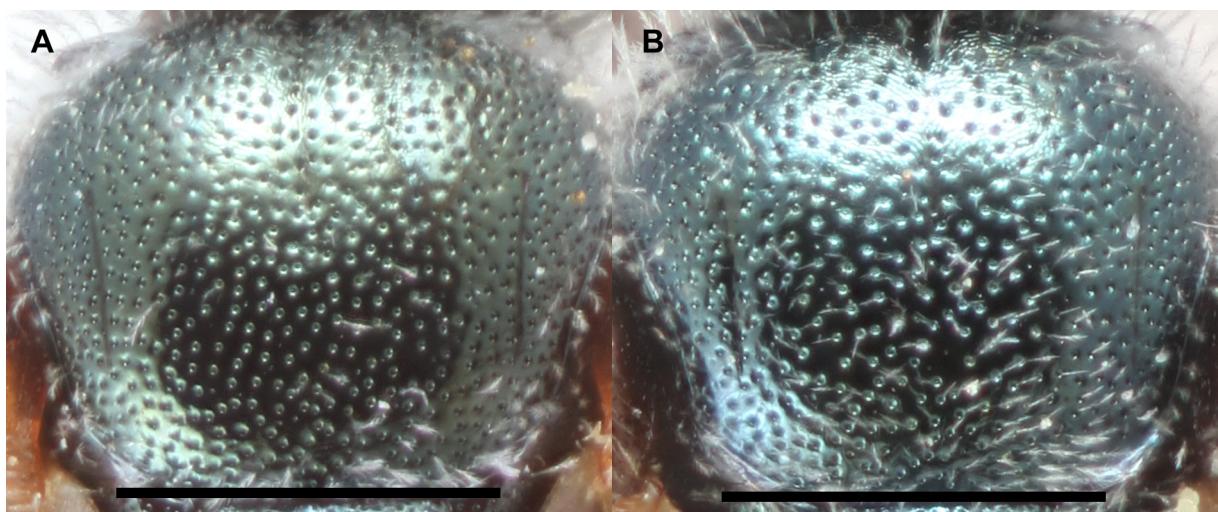

Fig. 120. Mesoscutum. **A.** *Lasioglossum ellisiae* (Sandhouse, 1924), ♂, evenly punctate with most IS = 1 PD. **B.** *L. diabolicum* sp. nov., ♂, more coarsely and unevenly punctate. Scale bars = 0.5 mm.

- Tegula relatively large, usually reaching mesoscutum posterior margin in dorsal view, and inner posterior margin concave, with a distinct posterior projection longer than 1 mesoscutum PD (as in Fig. 100B) *L. stictaspis* species complex [in part]

Discussion

Our revision of the *L. gemmatum* species complex in the western Nearctic region uncovered many new species and redefined the previously over-applied names *L. tegulariforme* and *L. hunteri* in a much more restricted sense. The true *L. tegulariforme* is a relatively uncommon species restricted to California and the Cascadia bioregion, while *L. hunteri* is considered a red-tailed form of *L. ellisiae*. While the identification of western *L. gemmatum* complex species is, unfortunately, much more difficult with the recognition of so many species, application of the new taxon concepts and use of the new identification keys will result in a better understanding of regional bee biodiversity and improve the accuracy and reliability of results from future studies.

The previously under-applied name *L. stictaspis*, conversely, may now be over-applied and require further revision. Prior to 2021, *L. stictaspis* was restricted to a small number of specimens with two submarginal cells in the forewing instead of the usual three (Sandhouse 1923). Gardner & Gibbs (2022) expanded *L. stictaspis* to include specimens with three submarginal cells, associated the female with *L. albuquerquense*, and recognised its range from Alberta and Saskatchewan to New Mexico and Texas. In the present work, we attempted to distinguish additional specimens from California, Arizona, and Mexico from *L. stictaspis* s. str., but were unable to find diagnostic characters that could be tested with other data and corroborate a species hypothesis. Some geographic trends in variation exist: for instance, no red-tailed *L. stictaspis* are known from east of the Rocky Mountains, while a majority of specimens from west of the Rocky Mountains and north of Mexico are red-tailed. Most specimens north of Mexico have a subapical band of tomentum on T3 and dense mesepisternum punctures, while most Mexican specimens lack subapical tomentum on T3 and have sparser mesepisternum punctures. Most specimens east of the Rocky Mountains have a smooth and dull metapostnotum, while coarse and shiny metapostnota become more common further west. However, the boundaries of this variation are extremely diffuse, such that any attempt to split *L. stictaspis* morphologically results in species that occur sympatrically throughout almost their entire range, and splitting by geography results in undiagnosable species. The multiple haplotypes within available COI barcodes also contain the full range of morphological variation. Given the presence of multiple overlapping COI haplotypes within morphologically similar specimens, including within the closely related *L. diabolicum* sp. nov., it is possible that COI barcode-based identification is confounded by incomplete lineage sorting or introgression (Gibbs 2018a; Patten *et al.* 2015). Additional, more robust genetic data may help resolve species limits within *L. stictaspis* s. lat.

Outside of *L. stictaspis*, there are several cases of allopatry within the *L. gemmatum* species complex, such that a known locality can drastically reduce the number of possible species identifications for an unknown specimen. The keys provided in this work are designed to work on specimens from anywhere in the Nearctic, and geographic differences are used to separate species where appropriate, but in some cases, geography can be a useful shortcut to identification. As an aid to geography-based identification, the major regions with distinct *L. gemmatum* species complex fauna are summarized in Fig. 77, and the species associated with each region are listed in Table 2. Notable patterns of allopatry include *L. angelicum* sp. nov. and *L. stictaspis* (allopatric in California and western low desert, respectively), *L. gloriosum* sp. nov. and *L. indagator* sp. nov. (allopatric in high and low deserts, respectively), *L. diabolicum* sp. nov. and *L. stictaspis* (partially allopatric; unique to high desert and eastern low desert + western Great Plains, respectively, but co-occurring in western low desert), and *L. helianthi* and *L. tegulariforme* (the only two species known from Cascadia, but co-occurring with several other species in California).

While some primarily Neotropical species were included in this work due to their occasional presence in the Nearctic, it is clear from examination of additional specimens that much work remains to be done in the Neotropics before the *L. gemmatum* species complex can be fully defined. Preliminary morphological sorting and DNA barcoding indicates the probable existence of at least 16 additional undescribed species in the Neotropics; it is even possible that the *L. gemmatum* species complex has a Neotropical centre of diversity. Many of these undescribed species are morphologically similar to *L. perparvum* (and *L. magnitegula* sp. nov. to a lesser extent) or belong to the *L. stictaspis* species complex. Future studies of the Neotropical *L. gemmatum* species complex should be prepared to deal with the *L. stictaspis* species complex and a likely *L. perparvum* species complex.

Future studies of the Nearctic *L. gemmatum* species complex should focus on the *L. stictaspis* species complex and testing for cryptic diversity within other species with multiple and/or shared COI haplotypes, such as *L. coactus* and *L. gaudiale*. *Lasioglossum ellisiae* may also harbour cryptic diversity, with some morphologically unusual females from southern Texas with a smooth propodeum, and a few unusual males from the eastern United States without facial tomentum. Studies of biological and behavioural aspects, such as nesting, foraging, social organization, bionomics, and dispersal would also be highly informative, given the relative dearth of such information for the *L. gemmatum* complex compared to other *Lasioglossum*. These studies could shed light on the function of the enlarged tegula and why its evolution appears to have led to such rapid diversification and dispersal throughout the New World.

Acknowledgments

The authors thank Cassidy Aguila for performing the DNA extractions and PCR for all DNA barcodes generated after the start of the pandemic and dealing with supply shortages and delays caused by the same. They also thank the numerous museum curators and independent researchers who lent specimens for study (listed in Material and methods). The lead author was supported by the University of Manitoba Graduate Fellowship, Douglas L. Campbell Graduate Fellowship, Entomological Society of Manitoba Graduate Student Scholarship, and USDA National Institute of Food and Agriculture award 2017-68004-26323 (PI: R. Isaacs). The authors acknowledge the financial support of the Natural Sciences and Engineering Research Council of Canada (NSERC), RGPIN-2018-05353 (awarded to J. Gibbs) and the University of Manitoba.

Supplementary files

Supp. file 1. Morphological character matrix used in conjunction with DNA barcodes to generate the phylogeny. Pink-shaded characters were recorded from female specimens and blue-shaded characters were from males. Variable characters are enclosed in curly brackets with all possible states. Unknown characters are marked with ?.

<https://doi.org/10.5852/ejt.2023.858.2041.8437>

Supp. file 2. Available 654-bp DNA barcodes of Nearctic *L. gemmatum* complex species. All sequences for each species or haplotype were merged into a single sequence with variable sites treated as ambiguities. Nucleotides diagnostic across all species are shaded black; nucleotides diagnostic within particular subsets are outlined.
