<urn:lsid:zoobank.org:author:744FA6FC-2D84-41B7-8A6C-C1611CC68EE1>

Abstract. The endophallic structure of the genus *Laius* is studied and discussed based on the examination of 19 species from Asia to the Indian Ocean. The structure contains two primary sclerites (named gonoporal piece and ligula), a secondary sclerite on the basal part of the gonoporal piece (named additional sclerite) in some species, and a membranous basal area closely covered with many spines (named spinous area). Five species groups are recognized based on the morphology of the endophallic sclerites. The sympatric species have different body sizes and quite distinguishable endophallic sclerites (= different species group), while the allopatric species have overlapping body sizes and similar endophallic sclerites (= same species group). Three new species are described and six previously known species are redescribed with endophallic sclerites, and the descriptions of endophallic sclerites of the remaining ten species are added. The larva of *Laius rodriguesensis* sp. nov. is also described. The genus *Nossibeus* Evers, 1994 is synonymised with *Laius* Guérin-Méneville, 1830.

Keywords. Melyridae, taxonomy, distribution, endophallus, new species.

Yoshitomi H. 2014. Comparative morphology of the endophallic structures of the genus *Laius* (Coleoptera, Melyridae), with the descriptions of three new species. *European Journal of Taxonomy* 97: 1–29. <http://dx.doi.org/10.5852/ejt.2014.97>

Introduction

Male genitalia are considered one of the most important diagnostic traits in insect systematics (Simmons 2014), and this also applies to the order Coleoptera (e.g., Sharp & Muir 1912). Some groups in this order have developed endophallic structures (e.g., sclerites, projections, small denticles), and these characters provide important information both taxonomically and phylogenetically. The endophallic structures are mainly observed in relatively large body-sized beetle families (e.g., Carabidae, Cerambycidae, Chrysomelidae), because it is necessary to evert and inflate the endophallus to observe the structures (Sasakawa 2005; Yamasako & Ohbayashi 2011). Therefore, it is difficult to dissect and observe the endophallic structures in smaller-sized groups.

The melyrid genus *Laius* Guérin-Méneville, 1830 is represented by about 30 species from the Pacific Islands, Indian Ocean, Australia, and the eastern coast of Africa (see Appendix); however, numerous species have been erroneously included in this genus and will be transferred to other genera (Plonski

2013; Wittmer 1997). The genus has a well-developed endophallic structure consisting of many small spines and some large sclerites, and these characters have been observed through the aedeagus (Wittmer 1997; Yoshitomi 2008; also see Fig. 2B). However, the characters could not be well understood or described.

The main aim of this study is to inspect the validity of endophallic structures for the recognition of species in this genus. I firstly define the terminology of the endophallic structures of the genus *Laius* and secondly describe the endophallic sclerites of 19 species, including the descriptions of three new species and redescriptions of six poorly known species.

Materials and methods

General observations and dissections were made under a Leica MZ95 stereomicroscope. Microstructures of dissected parts were studied in pure glycerine under an Olympus BH-2 compound microscope. After observation, the dissected parts were mounted on the same card with the specimen. Photographs were taken under a Leica MZ95 using a microscopy camera system (Nikon DS-Fi1-L2), and combined with the automontage software Combine ZM (Alan Hadley, UK). Some structures were observed with an SEM (Hitachi S-225) after coating with gold.

The endophallus was extracted from the ventral part of the aedeagal apex using a pin and tweezers. If the endophallus could not be extracted from the aedeagal apex, endophallic sclerites were directly removed from the endophallus. After observation, the structures were preserved in pure glycerine.

The holotypes and paratypes are preserved in the Ehime University Museum, Matsuyama (EUMJ), Naturhistorisches Museum Wien (NMW), Natural History Museum Basel (NHMB) and Bishop Museum, Hawaii (BPBM).

Abbreviations

Morphological abbreviations used for measurements are as follows (also see Fig. 2):

AL	=	aedeagal length
EL	=	length of elytra in suture
EW	=	maximum width of elytra
GL	=	length of gonoporal piece
HL	=	head length
HW	=	head width across eyes
L	=	length
LL	=	length of ligula
LW	=	width of ligula
PL	=	length of pronotum in median line
PW	=	maximum width of pronotum
TL	=	total length (HL+PL+EL)
W	=	width.

The average is given in parentheses after the range.

Results

Characteristics and terminology of endophallic structures

In the copulation position, only the endophallus of the male genitalia is engaged with the female structures (Fig. 1). Endophallic structures (Figs 1–2) consist of a membranous basal area (named spinous area),

two primary sclerites (named gonoporal piece and ligula), and a secondary sclerite in some species (named additional sclerite).

Spinous area (Figs 2A, 12D): membranous basal area, closely covered with many short spines (Fig. 12D), about $0.5 \times$ length of AL. The differences in this character between species cannot be observed, and the comparison and description of each species is not given in this study.

Gonoporal piece (Fig. 2C; *gp* in Figs 3–4): longest sclerite, about $0.6 \times$ length of AL, straight to rather curved, with pointed or rounded apex, closely covered with minute spines in basal portion of some species, projecting apically and straight from the apical portion of spinous area.

Ligula (Fig. 2D; *l* in Figs 3–4): straight to C-shaped curved sclerite, with pointed apex, shorter than gonoporal piece, projecting laterally from the apico-lateral portion of spinous area.

Additional sclerite (*as* in Figs 3–4): secondary sclerite situated in basal part of gonoporal piece, shorter than ligula, projecting laterally from the basal portion of gonoporal piece.

Taxonomy

Class Hexapoda Blainville, 1816
 Order Coleoptera Linnaeus, 1758
 Superfamily Cleroidea Latreille, 1802
 Family Melyridae Leach, 1815
 Subfamily Malachiinae Fleming, 1821

Genus *Laius* Guérin-Méneville, 1830

Laius Guérin-Méneville, 1830: 78 [Type species: *Laius cyaneus* Guérin-Méneville, 1830].
Megadeuterus Westwood, 1833: 678 [Type species: *Paussus flavigornis* Fabricius, 1801].
Rotamalachius Kôno, 1937 in Kôno & Esaki 1937: 121 [Type species: *Rotamalachius esakii* Kôno, 1937].
Nossibeus Evers, 1994: 173 [Type species: *Laius politus* Fairmaire, 1880]. syn. nov.

Remarks

The genus *Nossibeus* was erected for *Laius politus* Fairmaire, 1880 (Evers 1994). After observation of this species, including its endophallic structure, it was clear that this species cannot be recognised as another species of the genus *Laius*. In the present paper, *Nossibeus* Evers, 1994 is treated as a junior synonym of *Laius* Guérin-Méneville, 1830 (syn. nov.).

Laius baliensis sp. nov.
[urn:lsid:zoobank.org:act:9D51A886-E14B-4DE6-96C3-410AF3CBC669](https://lsid.zoobank.org/act:9D51A886-E14B-4DE6-96C3-410AF3CBC669)
 Figs 1, 3A, 5A–B, 7A, 8A, 9A, 13A–B

Laius sp. – Yoshitomi 2008: 289.

Diagnosis

Body small, TL = 4.10–4.46 mm in male, 4.35–4.75 mm in female; male antennomere III oval, deeply concave in dorso-mesal portion, L/W = 0.95; aedeagal apex rounded; gonoporal piece straight and slender; ligula slightly curved; additional sclerite absent.

Etymology

After the type locality, Bali Island, Indonesia.

Type material

Holotype

♂ (EUMJ), “Nusa Dua, South Island 8°48'6.81"S 115°14'16.07"E, Bali, INDONESIA 8. VIII. 2010 H. Yoshitomi leg.”.

Paratypes

1 ♂, 6 ♀♀ (EUMJ), same data as for the holotype; 6 ♂♂, 10 ♀♀ (EUMJ, NMW, BPBM, NHMB), “Nusa Dua, North Island 8°47'52.72"S 105°14'9.31"E, Bali, INDONESIA 7-8. VIII. 2010 H. Yoshitomi

leg.”; 3 ♀♀ (EUMJ), “Nusa Dua, Bali Indonesia 5-I-2000 H. Yoshitomi leg.”; 2 ♀♀ (EUMJ), ditto but collector “M. Satō”; 1 ♀ (EUMJ), ditto but collector “N. Ohbayashi”.

Description

Male

Body oblong, shining, densely covered with short black setae. Coloration of body black with strong bluish luster on head, pronotum and elytra; labrum, maxillary palpomere III and tarsi brown; antennomeres I–III and maxillary palpomeres I–II yellowish-orange.

Head slightly narrower than pronotum, densely punctate; vertex flat dorsally; eyes large, strongly prominent; HL/HW 0.73–0.82 (0.78). Antennae (Fig. 7A) stout; antennomere III (Fig. 8A) oval, deeply concave in dorso-mesal portion, L/W = 0.95; approximate ratio of each antennomeres ($n = 1$) as 8.0 : 1.0 : 6.0 : 2.2 : 2.0 : 1.8 : 1.8 : 2.0 : 1.8 : 2.8. Pronotum quadrate, widest near anterior margin, rounded and obscure in antero- and postero-lateral angles, punctate as in head; PW/PL 1.15–1.44 (1.26). Scutellum semicircular, covered with very fine punctures. Elytra oblong, subparallel-sided near base to apical 1/4; EL/EW 1.33–1.71 (1.50); EL/PL 2.50–2.89 (2.65); EW/PW 1.30–1.52 (1.41); TL/EW 2.33–2.93 (2.58). Legs relatively long and slender. Caudal margin of tergite VIII shallowly concave.

Aedeagus (Fig. 9A) about 1.12 mm, round at aedeagal apex. Gonoporal piece (Fig. 3A) straight, rather wide, 0.61 mm in GL; GL/AL 2.39. Ligula (Fig. 3A) short, curved in basal 1/3; LL 0.23 mm; LW 0.06 mm; LL/LW 3.73; GL/LL 2.68.

Female

Similar to male in general appearance; HL/HW 0.71–0.79 (0.76); PW/PL 1.20–1.36 (1.27); EL/EW 1.53–1.68 (1.59); EL/PL 2.65–2.93 (2.82); EW/PW 1.31–1.44 (1.39); TL/EW 2.60–2.82 (2.68). Antennae (Fig. 7A) stout; antennomere III short, L/W = 1.88; approximate ratio of each antennomeres ($n = 1$) as 8.8 : 1.0 : 4.2 : 2.4 : 2.2 : 2.2 : 2.0 : 1.8 : 2.0 : 2.0 : 3.0.

Measurements

Male ($n = 7$): TL 4.10–4.46 (4.27) mm; HL 0.80–0.90 (0.85) mm; HW 1.00–1.20 (1.10) mm; PW 1.08–1.30 (1.18) mm; PL 0.90–1.00 (0.94) mm; EL 2.40–2.60 (2.48) mm; EW 1.40–1.82 (1.67) mm. Female ($n = 7$): TL 4.35–4.75 (4.61) mm; HL 0.85–0.95 (0.90) mm; HW 1.15–1.25 (1.20) mm; PW 1.20–1.30 (1.24) mm; PL 0.90–1.00 (0.97) mm; EL 2.60–2.80 (2.73) mm; EW 1.60–1.80 (1.72) mm.

Distribution

Only known from the type locality, Indonesia (Bali Isl.).

Remarks

This species is similar to *Laius flavicornis* (Fabricius, 1801) and *L. sabangensis* Wittmer, 1985 in the shape of male antennomere III, and differs from them in the shape of endophallic sclerites and smaller body length.

Biological notes

This species was collected together with *Laius pankowi* Wittmer, 1999 and *L. satoi* Yoshitomi, 2008 at the same locality. Based on the data of Yoshitomi (2008) and the present study, *Laius baliensis* sp. nov. was collected in January and August, *L. pankowi* in January and December, and *L. satoi* in January, April, and August.

Laius andamanensis sp. nov.
[urn:lsid:zoobank.org:act:AB272070-CAEA-4964-8CFD-A219E93222F1](http://urn.lsid.zoobank.org:act:AB272070-CAEA-4964-8CFD-A219E93222F1)
Figs 3B, 5C–D, 7B, 8B, 9B, 12

Diagnosis

Male antennomere III distinctly projecting laterally, shallowly concave in dorso-mesal portion, L/W = 0.70; aedeagal apex concave; gonoporal piece straight and slender; ligula long and slightly curved; additional sclerite absent.

Etymology

After the type locality, Andaman Islands, India.

Paratypes

22 ♂♂, 10 ♀♀ (NHMB, EUMJ), same data as for the holotype.

Description**Male**

Body oblong, shining, densely covered with short black setae. Coloration of body black with dully bluish luster on elytra; labrum, maxillary palpomere I, and tarsi brown; antennomeres I–III yellowish-orange.

Head narrower than pronotum, very densely punctate; vertex slightly convex dorsally; eyes relatively large, prominent; HL/HW 0.76–0.90 (0.81). Antennae (Fig. 7B) long; antennomere III (Fig. 8B) transversal trapezoidal, distinctly projecting laterally, shallowly concave in dorso-mesal portion, L/W = 0.70; approximate ratio of each antennomeres ($n = 1$) as 8.3 : 1.0 : 5.0 : 2.0 : 2.2 : 2.0 : 2.0 : 2.0 : 2.0 : 3.5. Pronotum quadrate, widest near anterior margin, rounded and obscure in antero- and postero-lateral angles, punctate as in head; PW/PL 1.18–1.33 (1.24). Scutellum semicircular, covered with fine punctures. Elytra oblong, widest at apical 1/4; sides gradually expanded postero-laterally; EL/EW 1.36–1.55 (1.45); EL/PL 2.52–2.88 (2.67); EW/PW 1.38–1.55 (1.48); TL/EW 2.30–2.56 (2.44). Legs relatively long and slender; fore tibia (Fig. 12A) enlarged, deeply excavate. Caudal margin of tergite VII shallowly concave.

Aedeagus (Fig. 9B) about 1.13 mm, concave at aedeagal apex (Fig. 12C). Gonoporal piece (Fig. 3B) straight, slender, 0.74 mm in GL; GL/AL 2.39. Ligula (Fig. 3B) relatively long, slightly curved; LL 0.27 mm; LW 0.11 mm; LL/LW 2.58; GL/LL 2.71.

Female

Similar to male in general appearance. HL/HW 0.75–0.80 (0.79); PW/PL 1.18–1.30 (1.23); EL/EW 1.36–1.48 (1.41); EL/PL 2.44–2.73 (2.60); EW/PW 1.45–1.58 (1.51); TL/EW 2.30–2.43 (2.36). Antennae (Fig. 7B) long; antennomere III (Fig. 12B) distinctly expanded laterally, shallowly concave in dorsal portion, L/W = 2.42; approximate ratio of each antennomeres ($n = 1$) as 8.0 : 1.0 : 4.4 : 2.2 : 2.4 : 2.2 : 2.2 : 2.0 : 2.0 : 3.6

Measurements

Male ($n = 20$): TL 5.52–6.33 (5.79) mm; HL 1.00–1.15 (1.05) mm; HW 1.22–1.38 (1.30) mm; PW 1.48–1.75 (1.61) mm; PL 1.20–1.48 (1.29) mm; EL 3.28–3.75 (3.45) mm; EW 2.18–2.70 (2.38) mm. Female ($n = 6$): TL 4.43–4.96 (4.67) mm; HL 0.75–0.85 (0.81) mm; HW 1.00–1.08 (1.03) mm; PW 1.20–1.42 (1.32) mm; PL 1.00–1.20 (1.07) mm; EL 2.60–3.00 (2.79) mm; EW 1.85–2.15 (1.98) mm.

Distribution

Only known from the type locality, India (Andaman Islands).

Remarks

This is distinct species in having transversal antennomere III of male.

Laius rodriguesensis sp. nov.

Description

Male

Body oblong, shining, densely covered with short black setae. Coloration of body black with dully bluish luster on elytra; antennomeres I–III yellowish-orange, but anterior margin of antennomere I infuscate.

Head narrower than pronotum, very densely punctate; vertex slightly depressed dorsally; eyes relatively large, prominent; HL/HW 0.72–0.89 (0.78). Antennae (Fig. 7C) long; antennomere III (Fig. 8C) transverse, deeply concave in dorso-mesal portion, L/W = 0.74; approximate ratio of each antennomeres ($n = 1$) as 11.2 : 1.0 : 6.8 : 3.2 : 2.6 : 2.2 : 2.2 : 2.4 : 2.0 : 2.2 : 4.0. Pronotum quadrate, widest near anterior margin, rounded and obscure in antero- and postero-lateral angles; punctate as in head; PW/PL 1.33–1.49 (1.39). Scutellum semicircular, finely punctate. Elytra oblong, widest at apical 1/3; sides weakly expanded postero-laterally; EL/EW 1.31–1.50 (1.43); EL/PL 2.62–2.76 (2.69); EW/PW 1.31–1.42 (1.36); TL/EW 2.18–2.52 (2.42). Legs relatively long and slender. Caudal margin of tergite VII shallowly concave. Aedeagus (Fig. 9C) about 1.17 mm, round at aedeagal apex. Gonoporal piece (Fig. 3C) slightly curved, 0.63 mm in GL; GL/AL 1.81. Ligula (Fig. 3C) long, strongly curved in half; LL 0.30 mm; LW 0.11 mm; LL/LW 2.84; GL/LL 2.11.

Female

Similar to male in general appearance; bluish luster on elytra weak; coloration of antennomeres I–III black or dark brown; HL/HW 0.74–0.95 (0.84); PW/PL 1.32–1.42 (1.37); EL/EW 1.29–1.47 (1.39); EL/PL 2.47–2.86 (2.68); EW/PW 1.30–1.48 (1.41); TL/EW 2.25–2.47 (2.39). Antennae (Fig. 7C) long; antennomere III short, L/W = 2.16; approximate ratio of each antennomeres ($n = 1$) as 8.6 : 1.0 : 4.4 : 2.0 : 2.0 : 1.8 : 1.8 : 2.0 : 2.0 : 2.0 : 3.8.

Measurements

Male ($n = 5$): TL 5.50–5.75 (5.64) mm; HL 1.00–1.20 (1.08) mm; HW 1.30–1.45 (1.38) mm; PW 1.60–1.83 (1.72) mm; PL 1.20–1.30 (1.24) mm; EL 3.20–3.40 (3.32) mm; EW 2.20–2.60 (2.33) mm. Female ($n = 10$): TL 4.10–4.68 (4.41) mm; HL 0.80–1.00 (0.88) mm; HW 1.00–1.10 (1.05) mm; PW 1.20–1.38 (1.32) mm; PL 0.90–1.00 (0.96) mm; EL 2.35–2.80 (2.57) mm; EW 1.70–2.00 (1.85) mm.

Larvae

Coloration of head capsule and urogomphi dark brown; thoracic and abdominal segments and legs cream. Head capsule (Fig. 10B) suboblong, L/W = 1.3; four pairs of stemmata situated near antero-lateral corners. Antennae missing. Labrum (Fig. 11B) with a pair of long lateral and five pairs of short mesal setae in anterior portion; anterior margin of epipharynx bearing short stout setae. Maxillae (Fig. 11A) bearing long setae in antero-lateral portion. Mandibles (Fig. 11C) with two apical teeth; mola with two short teeth. Labium (Figs 10C, 11A) relatively wide, with 2-segmented palpi. Thorax weakly sclerotized, widest at posterior part of metathorax; pronotum with two pairs of longitudinal sclerotized bands in mesal portion, bearing short setae in lateral and mesal portions. Abdomen (Fig. 10A) weakly sclerotized, subparallel-sided, bearing short setae in lateral and postero-mesal portions. Urogomphi (Fig. 10D–F) subparallel-sided, closely covered with long setae, simply bifurcate in apical 1/2, upturned in apical portions, pointed at apices, with some very long hairy setae in apical parts. Legs relatively long.

Additional material examined

2 Larvae (NMW, in ethanol), “MAURITIUS Rodrigues Anse Fumier 10.05.2008, leg. M. Madl”.

Distribution

Only known from the type locality, Republic of Mauritius (Rodrigues Isl.).

Remarks

This species is closely related to *Laius madli* Yoshitomi, 2010 known from Mauritius, but differs from the latter in the following characteristics: 1) ligula strongly curved in middle portion (rather weakly curved

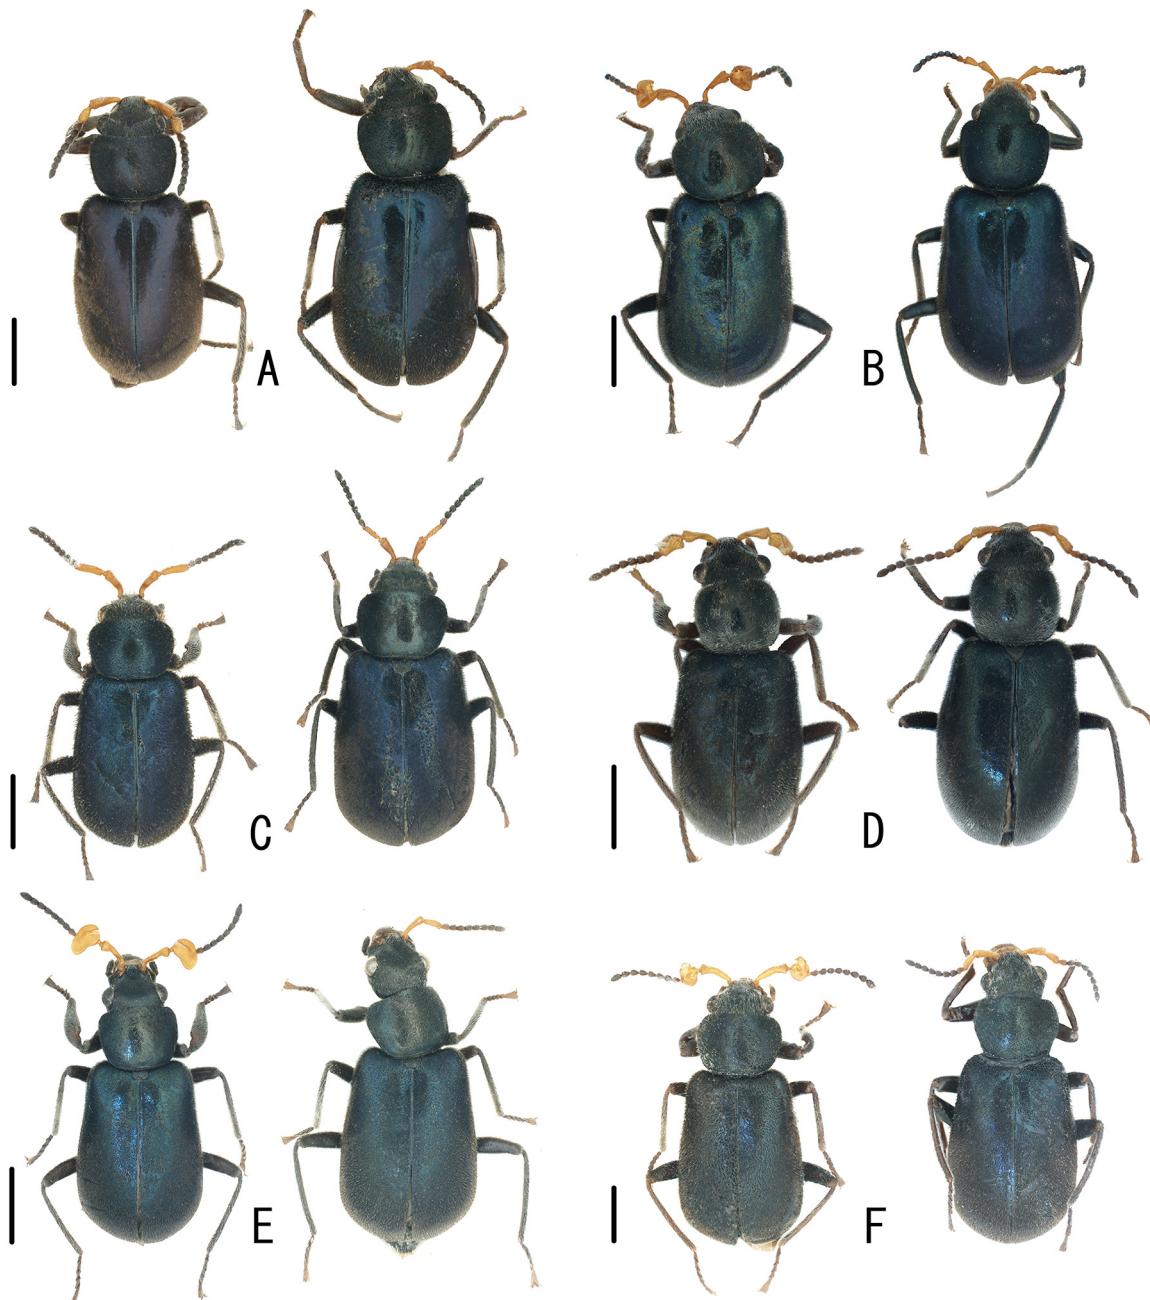

Fig. 6. Dorsal habitus of *Laius* spp. (left: ♂; right: ♀). **A.** *Laius maai* Wittmer, 1973 (paratype). **B.** *L. marchei* Pic, 1922. **C.** *L. politus* Fairmaire, 1880. **D.** *L. sabangensis* Wittmer, 1985 (paratype). **E.** *L. sericatus* Champion, 1924. **F.** *L. submariniformis* Wittmer, 1985 (paratype). Scale bars = 1.0 mm.

basally in *madli*); 2) male antennomere III projecting laterally, transverse, L/W = 0.7 (antennomere III slightly projecting laterally, L/W = 0.9 in *madli*).

The larvae of two Japanese species, *L. asahinai* Nakane, 1955 and *L. miyamotoi* Nakane, 1955, were described by Satô (1964) and Asano & Kojima (2009). The larva of *L. rodrigesensis* sp. nov. is similar to those of the aforementioned species, and differs from them in that the teeth of the mola are rather short, and that the head is narrower.

Figs 3D, 6A, 7D, 8D, 9D

Laius maai Wittmer, 1973: 336.

Type material

Paratypes 6 ♂♂, 2 ♀♀, (BPBM), “New Guinea: NE Sarmi, W Hollandia”, “20.-23.7.1959 T. C. Maa”.

Redescription

Male

HL/HW 0.82; PW/PL 1.36; EL/EW 1.51; EL/PL 2.95; EW/PW 1.43; TL/EW 2.46. Antennae (Fig. 7D) long; antennomere III (Fig. 8D) oblong, widened in basal 1/3, L/W = 2.08; approximate ratio of each antennomeres ($n = 1$) as 7.4 : 1.0 : 3.6 : 2.1 : 1.9 : 1.9 : 1.7 : 1.6 : 1.7 : 1.9 : 3.1. Caudal margin of tergite VII concave. Aedeagus (Fig. 9D) about 1.32 mm, concave at aedeagal apex. Gonoporal piece (Fig. 3D) straight, slender, with long and straight basal projection, 0.77 mm in GL; GL/AL 2.01. Ligula (Fig. 3D) relatively long, slightly curved; LL 0.29 mm; LW 0.09 mm; LL/LW 3.06; GL/LL 2.65.

Female

HL/HW 0.78–0.81 (0.80); PW/PL 1.31–1.37 (1.33); EL/EW 1.42–1.66 (1.50); EL/PL 2.70–2.96 (2.83); EW/PW 1.35–1.46 (1.41); TL/EW 2.39–2.67 (2.48). Antennae (Fig. 7D) long; antennomere III short, L/W = 1.88; approximate ratio of each antennomeres ($n = 1$) as 11.3 : 1.0 : 5.3 : 2.8 : 3.0 : 3.0 : 3.0 : 2.5 : 2.8 : 2.5 : 4.5.

Measurements

Male ($n = 1$): TL 5.05 mm; HL 0.90 mm; HW 1.10 mm; PW 1.43 mm; PL 1.05 mm; EL 3.10 mm; EW 2.05 mm. Female ($n = 4$): TL 4.50–4.68 (4.58) mm; HL 0.80–0.85 (0.82) mm; HW 1.00–1.05 (1.03) mm; PW 1.30–1.33 (1.31) mm; PL 0.95–1.00 (0.98) mm; EL 2.70–2.90 (2.78) mm; EW 1.75–1.90 (1.85) mm.

Distribution

New Guinea.

Kagoshima, Japan 25-26. V. 2013 N. Ohbayashi leg.”; 2 ♂♂, 3 ♀♀ (EUMJ), “Hachijo Is. Mitsune 20. V. 2001 Y. Kawabata”. Others see Yoshitomi & Lee (2010).

Description of endophallic sclerites

Gonoporal piece (Fig. 3J) straight, slender, 0.81 mm in GL; GL/AL 3.96. Ligula (Fig. 3J) short, slightly curved; LL 0.17 mm; LW 0.04 mm; LL/LW 3.88; GL/LL 4.71.

Distribution

Japan (Honshu, Izu Isls. [Oshima, Miyake-jima, Hachijo-jima], Shikoku, Kyushu, Shimo-koshiki-jima, Yakushima).

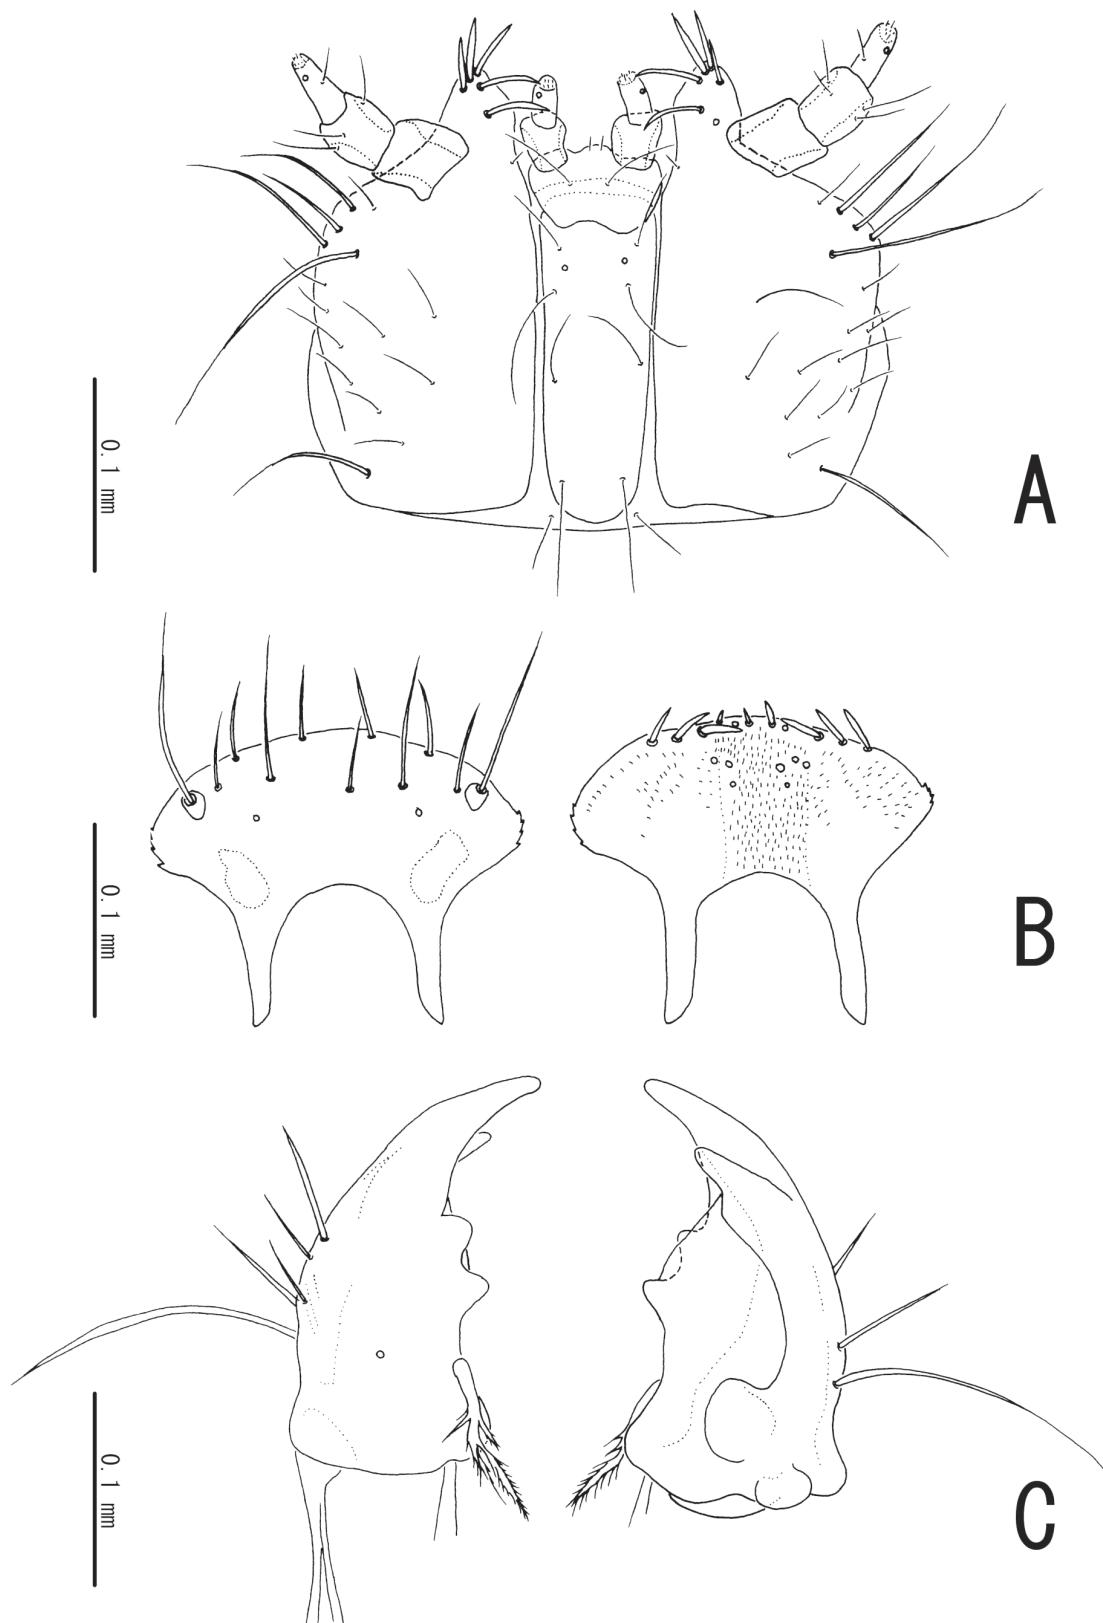

Fig. 11. Larva of *Laius rodriquesensis* sp. nov. **A.** Maxillae and labium in ventral view. **B.** Labrum in dorsal (left) and ventral (right) views. **C.** Mandible in dorsal (left) and ventral (right) views.

Remarks

This is the first record of this species from Oshima, Miyake-jima, and Shimo-koshiki-jima. This species is distributed in the northernmost area in the genus, and widely spread. The local variation of the endophallic sclerites was not observed in this study, but the specimens in the Izu Isls. have somewhat darker elytral coloration.

Laius etsukoae Satô, Yoshitomi & Ohbayashi, 2006

Material examined

1 ♂ (EUMJ), “Taitung, TAIWAN Is. Lutao 4-6. IV. 2012 N. OHBAYASHI leg.”. Other material studied is already mentioned in Yoshitomi & Lee (2010).

Description of endophallic sclerites

Gonoporal piece (Fig. 4H) curved, rather wide, 0.67 mm in GL; GL/AL 1.68. Ligula (Fig. 4H) long, slightly curved; LL 0.38 mm; LW 0.08 mm; LL/LW 4.60; GL/LL 1.74. Additional sclerite (Fig. 4H) present, 0.09 mm.

Remarks

Yoshitomi & Lee (2010) pointed out that this species has local variations between the populations from mainland Taiwan, Lutao and Lanyu Isls. in body size and elytral luster. For the present study, I examined the endophallic structures of these populations, and it became clear that they certainly belong to the same species because of the highly similar features of the endophallic structures.

Discussion

The endophallic structure of the genus *Laius*

The results in this paper show that the endophallic structures of the genus *Laius* are important taxonomically. For close and precise examination of the endophallic sclerites, it is necessary to remove the sclerites from the aedeagus directly or extract them from the ventral part of the aedeagal apex.

Based on the constructions of endophallic sclerites in 19 species, the genus is subdivided into the following five species groups:

- Group 1 (*sericatus, etsukoae, keiichii, taiwanus, sabangensis*): additional sclerite present.
- Group 2 (*maai, marchei, submariniformis, flavigornis*): gonoporal piece with basal projection.
- Group 3 (*baliensis* sp. nov., *andamanensis* sp. nov., *rodriguesensis* sp. nov., *politus, sericatus, asahinai, lutaoensis, miyamotoi, madli*): ligula short, curved.
- Group 4 (*satoi*): ligula long and straight; gonoporal piece long.
- Group 5 (*pankowi*): ligula long, straight, microcuticulate in apical portion.

Distribution

The species of *Laius* inhabit rocky seashores (Fig. 13A), and 1–3 species are distributed in the same place. Table 1 shows the distribution pattern in five areas (Japan, Taiwan, Palawan Isl., Palau, and Bali Isl.). Two species in Taiwan (Lutao Isl.) and the Philippines (Palawan Isl.), and three in Indonesia (Bali Isl.) are sympatric, and have different body sizes and endophallic structures (= different species group) in each area. On the other hand, two species in Japan and Palau are allopatric (or parapatric), their body sizes overlap and the endophallic structures are also similar to each other (= same species group) in each area.

All members of *Laius* have developed hind wings and are capable of flying, and in fact they often fly in the field. In addition, they are able to stay submerged in seawater for up to 30 hours (Hashimoto

Table 1. Distribution of *Laius* spp. in five areas.

Distribution		Pattern	Species	Species group	Measurement in male (mm)				Reference
	Locality				TL	AL	GL	LL	
Japan	Honshu to Yakushima	allopatric	<i>asahinai</i>	3	3.95–4.65 (4.27)	1.19	0.81	0.17	Yoshitomi & Lee 2010
	Ryukyu Isls.		<i>miyamotoi</i>	3	3.50–4.20 (3.88)	1.17	0.72	0.15	Yoshitomi & Lee 2010
Taiwan	Lutao Isl.	sympatric	<i>taiwanus</i>	1	3.90–4.88 (4.18)	1.03	0.67	0.38	Yoshitomi & Lee 2010
			<i>lutaoensis</i>	3	4.80–5.45 (5.18)	1.31	0.64	0.23	Yoshitomi & Lee 2010
Philippines	Palawan	sympatric	<i>submariniformis</i>	2	4.90–6.33 (5.60)	1.37	0.77	0.37	present study
			<i>sabangensis</i>	1	4.03–4.73 (4.23)	0.94	0.72	0.41	present study
Palau	Merir, Sonsorol Isls.	allopatric	<i>etsukoae</i>	1	3.4–4.5	1.00	0.59	0.24	Satô <i>et al.</i> 2006
	Peleliu Isl.		<i>keiichii</i>	1	3.8	1.19	0.54	0.31	Satô <i>et al.</i> 2006
Indonesia	Bali Isl.	sympatric	<i>satoi</i>	4	5.7	1.53	0.94	0.49	Yoshitomi 2008
			<i>pankowi</i>	5	6.13–6.55 (6.34)	1.58	1.04	0.77	Yoshitomi 2008
			<i>baliensis</i>	3	4.10–4.46 (4.27)	1.12	0.61	0.23	present study

1970). Therefore it is supposed that the distribution of each species is widely spread through flight and tidal currents. However, most of the species show narrow distributions (see Appendix). The genus *Aegialites* Mannerheim, 1853 (Coleoptera, Salpingidae, Aegialitinae) also lives in rocky seashores, and the distribution of each of its species is generally restricted as the ones of the species of the genus *Laius* (see Doyen 1976; Zerche 2004). However, *Aegialites* is flightless with degenerated hind wings, and its distribution is limited in the Northern Pacific (latitude c. 30–60°N; Northern Japan, Kuril Isls., to North America). The speciation and distribution pattern of *Laius* provide interesting zoogeographical and evolutionary themes.

Acknowledgements

I thank Dr. Manfred Jäch (NMW), Dr. Michael Geiser (NHMB), Mr. Ryo Ogawa (Kobe Univ.), Dr. Junsuke Yamasako and Dr. Nobuo Ohbayashi (both EUMJ), Miss Makoto Asano, Mr. Shepherd Myers (BPBM), Dr. Nugroho Susetya Putra (Gadjah Mada University), and the late Dr. Masataka Satô for supplying the materials used in this paper, and Mr. Dennis Murphy (The United Graduate School of Agricultural Sciences, Ehime University) for his critical reading of the draft. A part of this study is supported by the KAKENHI (24510333; head investigator: H. Kojima).
