# Scandinavian *Oncophorus* (Bryopsida, Oncophoraceae): species, cryptic species, and intraspecific variation

Lars HEDENÄS

Swedish Museum of Natural History, Department of Botany,  
Box 50007, SE-104 05 Stockholm, Sweden.

E-mail: [lars.hedenas@nrm.se](mailto:lars.hedenas@nrm.se)

**Abstract.** Scandinavian members of the acrocarpous moss genus *Oncophorus* were revised after field observations had suggested unrecognized diversity. Based on molecular (nuclear: internal transcribed spacers 1 and 2, ITS; plastid: *trnG*<sub>UCC</sub> G2 intron, *trnG*, *rps4* gene + *trnS-rps4* spacer, *rps4*) and morphological evidence, four morphologically distinguishable species are recognized, *Oncophorus elongatus* (I.Hagen) Hedenäs, *O. integerrimus* Hedenäs sp. nov. (syn. *O. virens* var. *elongatus* Limpr.), *O. virens* (Hedw.) Brid., and *O. wahlenbergii* Brid. (*O. sardous* Herzog, syn. nov.). *Oncophorus elongatus* was earlier recognized, but much of its variation was hidden within *O. wahlenbergii*. Its circumscription is here expanded to include plants with long leaves having mostly denticulate or sharply denticulate upper margins and with long and narrow marginal cells in the basal portion of the sheathing leaf lamina. The new species *O. integerrimus* sp. nov. differs from *O. virens* in having more loosely incurved leaves and entire or almost entire upper leaf margins. Besides these characters, the species in the respective pairs differ in quantitative features of the leaf lamina cells. Several cryptic entities were found, in several cases as molecularly distinct as some of the morphologically recognizable species, and phylogeographic structure is present within *O. elongatus* and *O. virens*.

**Keywords.** Geographic differentiation, habitat differences, morphology, *Oncophorus integerrimus* Hedenäs sp. nov., Principal Component Analysis.

Hedenäs L. 2017. Scandinavian *Oncophorus* (Bryopsida, Oncophoraceae): species, cryptic species, and intraspecific variation. *European Journal of Taxonomy* 315: 1–34. <https://doi.org/10.5852/ejt.2017.315>

## Introduction

A significant proportion of species diversity is either not yet recognized, such as undescribed species, or hidden within morphologically closely similar or virtually identical species (Hawksworth 2001; Bickford *et al.* 2006; Crawford & Stuessy 2016). During the last years this has been shown repeatedly for different bryophyte genera (Heinrichs *et al.* 2010; Carter 2012a, 2012b; Buchbender *et al.* 2014; Hedenäs *et al.* 2014; Draper *et al.* 2015). *Oncophorus* Brid. (von Bridel 1826) is another example of a moss genus for which species' circumscriptions are still unclear, and where it has not yet been tested if the many existing names at levels below the species reflect high intraspecific variation (e.g., Limpricht 1886; Mönkemeyer 1927; Nyholm 1987). *Oncophorus* (Dicranales: Oncophoraceae; Goffinet *et al.* 2008; Stech & Frey 2008; Frey & Stech 2009) includes acrocarpous species with leaves having a sheathing basal portion and a mostly long, gradually tapering, and narrowly triangular to almost linear

upper portion. Species of *Oncophorus* are frequent in many wet or humid habitats in arctic to temperate regions of the Northern Hemisphere, and in addition some species occur in Sri Lanka or temperate areas of the Southern Hemisphere (Frahm *et al.* 1998; Frey & Stech 2009).

In a relatively recent global treatment of *Oncophorus*, Frahm *et al.* (1998) recognized six species, down from twelve before their revision. Since then additional species were distinguished or described (Hedenäs 2005; Hedderson & Blockeel 2006), and Frey & Stech (2009) recognized nine species in the genus. Two of the species that Frahm *et al.* (1998) recognized, *O. virens* (Hedw.) Brid. (von Bridel 1826) and *O. wahlenbergii* Brid. (von Bridel 1826) are widespread and frequent in many areas of northern and central Scandinavia, but are rare in the south of Scandinavia (e.g., Hallingbäck *et al.* 2006). Some of the Scandinavian material considered by Frahm *et al.* (1998) as belonging to *O. wahlenbergii* has later been recognized as a species of its own, *O. elongatus* (I.Hagen) Hedenäs, restricted mainly to the mountains and the far north (Hedenäs 2005). Hagen (1899) originally distinguished this taxon by its large, yellow-green, incoherent tufts, leaves 5.3 mm long and 1 mm wide, and a long-excurrent leaf costa.

Significant additional variation was observed during fieldwork in Norway and Sweden. Much of the variation could be interpreted as habitat-induced, but some was not possible to explain by this alone. For example, strikingly large plants forming lax tufts and with morphological affinities to *O. wahlenbergii* or *O. elongatus* occur along rocky shores of the Bothnian Sea and Bothnian Bay in Sweden, and *O. virens* s. lat. varies from tiny phenotypes in late snow-beds to large and lax phenotypes in fens. Finally, two specimens of *O. virens* s. lat. with very different appearances were found growing close to each other in the same habitat on Mt. Åreskutan in Jämtland (C. Sweden), suggesting that some of the morphological variation was likely to have a genetic basis.

Information from morphology alone is evidently insufficient to interpret the variation within Scandinavian *Oncophorus*, or the taxonomy would already be clear and agreed on. Here, an approach including a wide molecular sampling of the Scandinavian taxa is combined with detailed morphological studies to explore (1) the circumscriptions of the so-far accepted taxa, and (2) whether additional species occur in the area. Based on the gathered information the circumscriptions of *O. elongatus* and *O. wahlenbergii* are considerably emended and *O. virens* s. lat. is divided into two species. In addition, several cryptic entities were detected and are discussed.

## Material and methods

### Study species and material

For the molecular evaluation, 24 Scandinavian specimens of *O. elongatus*, 22 of *O. wahlenbergii*, and 48 of *O. virens* s. lat. were studied. The species were sampled to represent different areas and environments in Scandinavia, as well as to cover the known morphological variation. Two specimens of the recently described species *Oncophorus dendrophilus* Hedd. & Blockeel (Hedderson & Blockeel 2006), from Cyprus and Crete, and two specimens of each of two other members of the genus, *O. crispifolius* (Mitt.) Lindb. (Lindberg 1872) and *O. rauei* (Austin) Grout (Grout 1937), were included for an assessment of the positions of *O. virens* and *O. wahlenbergii* within the genus. Based on Stech *et al.* (2012) two specimens of each of the two species *Cynodontium strumiferum* (Hedw.) Lindb. (Lindberg 1864) and *Rhabdoweisia fugax* (Hedw.) Bruch & Schimp. (Bruch & Schimper 1846), which appear in the clade sister to *Oncophorus*, were used as outgroup. The molecularly studied specimens are listed in Table 1.

The morphological analysis was based on specimens of *O. elongatus*-*O. wahlenbergii* and *O. virens* s. lat. that were included in the molecular analysis, whereas the geographical distribution of the species that were recognized for Scandinavia was mapped based on all Scandinavian material present in the Swedish Museum of Natural History (S). All Scandinavian S specimens were checked for their identity

based on the results of the present study. Detailed information on these specimens is available at: <http://herbarium.nrm.se/>

### Molecular methods

Total DNA was extracted using the DNeasy® Plant Mini Kit for DNA isolation from plant tissue (QIAGEN) or the KingFisher Duo magnetic particle processor and the KingFisher Pure DNA Plant Kit (Thermo Fisher Scientific). Double stranded DNA templates were prepared by polymerase chain reaction (PCR). PCR was performed using Illustra™ Hot Start Mix RTG (GE Healthcare) in a 25 µl reaction volume according to the manufacturer's instructions.

Initially, variation in the nuclear internal transcribed spacers 1 and 2 (ITS) and a portion of glyceraldehyde 3-phosphate dehydrogenase (*gpd*), and the plastid *atpB-rbcL* spacer (*atpB-rbcL*), *rpl16* G2 intron (*rpl16*), the *rps4* gene + *trnS-rps4* spacer (*rps4*), *trnG<sub>UCC</sub>* G2 intron (*trnG*), and *trnL<sub>UAA</sub>* intron plus *trnL<sub>UAA</sub>-trnF<sub>GAA</sub>* spacer (*trnL-trnF*) were explored for 4–5 specimens each of *O. elongatus*, *O. virens* s. lat., and *O. wahlenbergii*. The three most variable ones, ITS, *trnG*, and *rps4* were selected for the investigation. ITS was amplified with the primers '18SF' and '26SR' (Rydin *et al.* 2004), in a few cases with the internal primers '5.8F-Chrys' (Howis *et al.* 2009) and '5.8SRPEny' (Nylinder *et al.* 2013), *trnG* with the primers 'trnGf' and 'trnGr' (Pacak & Szweykowska-Kulińska 2000), and *rps4* with 'rps5F' (Nadot *et al.* 1994) and 'trnS' (Souza-Chies *et al.* 1997). For all three markers the following PCR program was used: 5 min at 95°C followed by 4 cycles of 30 sec at 95°C, 30 sec at 57°C, 1 min at 72°C, 4 cycles of 30 sec at 95°C, 30 sec at 55°C, 1 min at 72°C and 34 cycles of 30 sec at 95°C, 30 sec at 57°C, 1 min at 72°C and a final elongation step of 8 min at 72°C.

Twenty µl of each amplified fragment were cleaned using a mixture of 20 units of Exonuclease I from *E. coli* and 4 units of FastAP™ Thermosensitive Alkaline Phosphatase (Fermentas LIFE SCIENCE), mixed and incubated at 37°C for 30 min and inactivated at 80°C for 15 min. Cycle sequencing was performed using the ABI BigDye Terminator Kit (Applied Biosystems) according to the instructions on the kit (BDT ver. 3.1), and the sequencing products were cleaned using the DyeEx® 96 Kit (QIAGEN). The same primers as for the initial PCR were used. Sequencing products were resolved on an ABI3130xl automated sequencer. Double stranded sequencing was performed.

### Sequence editing and analysis of molecular data

Nucleotide sequence fragments were edited and assembled for each DNA region using PhyDE® 0.9971 (<http://www.phyde.de/index.html>). The assembled sequences were manually aligned in PhyDE®. Regions of partially incomplete data in the beginning and end of the sequences were identified and excluded from subsequent analyses. Gaps were coded as informative by simple indel coding (Simmons & Ochoterena 2000), using SeqState (Müller 2005). The sequence alignments used in the analyses are available on request. European Nucleotide Archive (EMBL-ENA) accession numbers are listed in Table 1.

Paralogous ITS haplotypes are rarely encountered in bryophytes (but see Košnar *et al.* 2012). However, the ITS chromatograms generated in this study did not show 'messy' patterns or noise that could suggest paralogy, and the 5.8S gene was invariable among the samples (cf., Shaw *et al.* 2002; Feliner & Rosselló 2007). The revealed ITS variation is thus interpreted as being among homologous haplotypes.

The program TCS (Clement *et al.* 2000) with a cut-off level of 0.95 was used to evaluate relationships among specimens in a haplotype context. Reticulation was revealed in the haplotype networks based on either ITS or chloroplast data. Because reticulation occurs a split network was computed with the NeighborNet (NN) method as implemented in SplitsTree 4.12.6 (Huson & Bryant 2006) to visualize similarities or relationships among samples. A Jackknife analysis (1000 replications) was performed with

the program TNT (Goloboff *et al.* 2003) to test whether supported lineages exist among the studied *Oncophorus* species in a phylogenetic tree context. ITS and chloroplast data were analysed separately, since both visual inspection of the split networks, Jackknife trees, and the ILD test (Farris *et al.* 1995; 200 replicates,  $p = 0.005$ ) indicated that the two are incongruent.

### Morphological study and analysis of measurements

After the molecular relationships among the studied *O. elongatus*, *O. wahlenbergii*, and *O. virens* s. lat. specimens had been clarified, the morphology of selected specimens belonging to the distinguished molecular entities was studied. Earlier studies (e.g., Frahm *et al.* 1998) based only on morphology had clearly separated *O. elongatus*-*O. wahlenbergii* from *O. virens* s. lat., but had failed to correctly identify the further morphological entities distinguished by the molecular study. Therefore, an approach including both standard comparisons of qualitative and quantitative characters and the quantification of vegetative leaf size and especially leaf cell size and shape was used. Since vegetative leaves are invariably present in a plant it was expected that the latter approach, which had not been explored previously within *Oncophorus*, would reveal quantitative differences supporting the molecularly recognized entities.

Among molecularly identified *O. virens* s. lat., the two main entities *O. virens* s. str. and *O. integerrimus* Hedenäs (sp. nov.; see below) were sampled with 10 specimens each. The seemingly more heterogeneous *O. elongatus* was sampled with 18 specimens and *O. wahlenbergii* with 17 specimens. These 17 specimens included those belonging to the two small, molecularly well-supported *O. wahlenbergii* clades B and C in Fig. 1. The morphologically sampled specimens are indicated with an asterisk (\*) in Table 1. For each of these specimens, three vegetative leaves were sampled from two shoots (2 leaves from one stem and 1 from the other, to avoid sampling all leaves from an untypical shoot for the specimen). For each leaf, length and maximal width was measured, and the length, width, and length-to-width ratio of 20 cells in the upper acumen, 20 in the lower acumen, and 20 in the sheathing basal lamina were recorded. Temporary images of the leaves were taken through an Olympus BX43 microscope using an Olympus SC50 digital camera and the Olympus cellSens Standard 1.13 software (Olympus Corporation) for automatic and continuous image stacking. Measurements were then made from these leaf and cell images, using the Olympus cellSens Standard 1.13 software.

Comparisons among the four entities within *O. elongatus*-*O. wahlenbergii* and between the two within *O. virens* s. lat., respectively, are based on two approaches. First, the cell measurements were compared between the entities within each of the two groups. Shapiro Wilks W-test (normality) and Levenes test (homogeneity of variance) were both statistically significant, and inspection of the distributions of residuals in preliminary ANOVAs (normality) showed that the data do not meet the criteria of normality and homogeneity of variance. Thus, for *O. elongatus*-*O. wahlenbergii* the nonparametric Kruskal-Wallis test for multiple comparisons and for *O. virens* s. lat. the nonparametric Mann Whitney-U-test for comparing two groups were used to compare the cell measurements among or between the entities, respectively. Second, the measurements of the individual leaves (length, width, and the mean cell length, cell width, and cell length-to-width ratio, at each of the three positions in the leaf; in total 11 parameters) were subjected to a Principal Component Analysis (PCA) to see whether the combined information corresponds with the molecularly identified entities. All statistical calculations were made in STATISTICA 12 (StatSoft 2013).

### Herbarium data

Herbarium acronyms follow *Index Herbariorum* (Thiers continuously updated). For specimens citations, double quotes “...” indicates that citation is exactly as on label; square brackets [...] indicates that information is interpreted from label data.

## Results

### *Molecular relationships*

The total number of aligned ITS sites in the 100 studied *Oncophorus* specimens, and outgroup of two *Cynodontium strumiferum* and two *Rhabdoweisia fugax* specimens, after deletion of regions at the beginnings and ends that were incomplete for some specimens, was 1022. Of these, 212 sites were variable (122 in the species complexes around *Oncophorus virens* and *O. wahlenbergii*), with 95.8% (95.1%) of the variable ones parsimony-informative; 181 (85) indels were present, with 93.9% (96.5%) informative. For *trnG* the length was 618, 91 (63) were variable, and 96.7% (95.2%) of these were parsimony-informative; 25 (10) indels with 92% (90%) informative. For *rps4* the length was 628, 73 (35) were variable, and 98.6% (97.1%) of these were parsimony-informative; 4 (3) indels with 100% (100%) informative. The sequence lengths for the species were: *Oncophorus crispifolius* (n = 2): 827 (ITS), 574 (*trnG*), 621 (*rps4*); *O. dendrophilus* (2): 818, 581, 628; *O. elongatus* (24): 812–823, 588, 621; *O. rauei* (2): 819–823, 579, 610; *O. virens* (22): 835–838, 578–596, 620; *O. wahlenbergii* (22): 803–826, 581–582, 612; *O. integerrimus* sp. nov. (26): 837–840, 579, 627; *Cynodontium strumiferum* (2): 773, 576, 621; *Rhabdoweisia fugax* (2): 782–784, 571, 621.

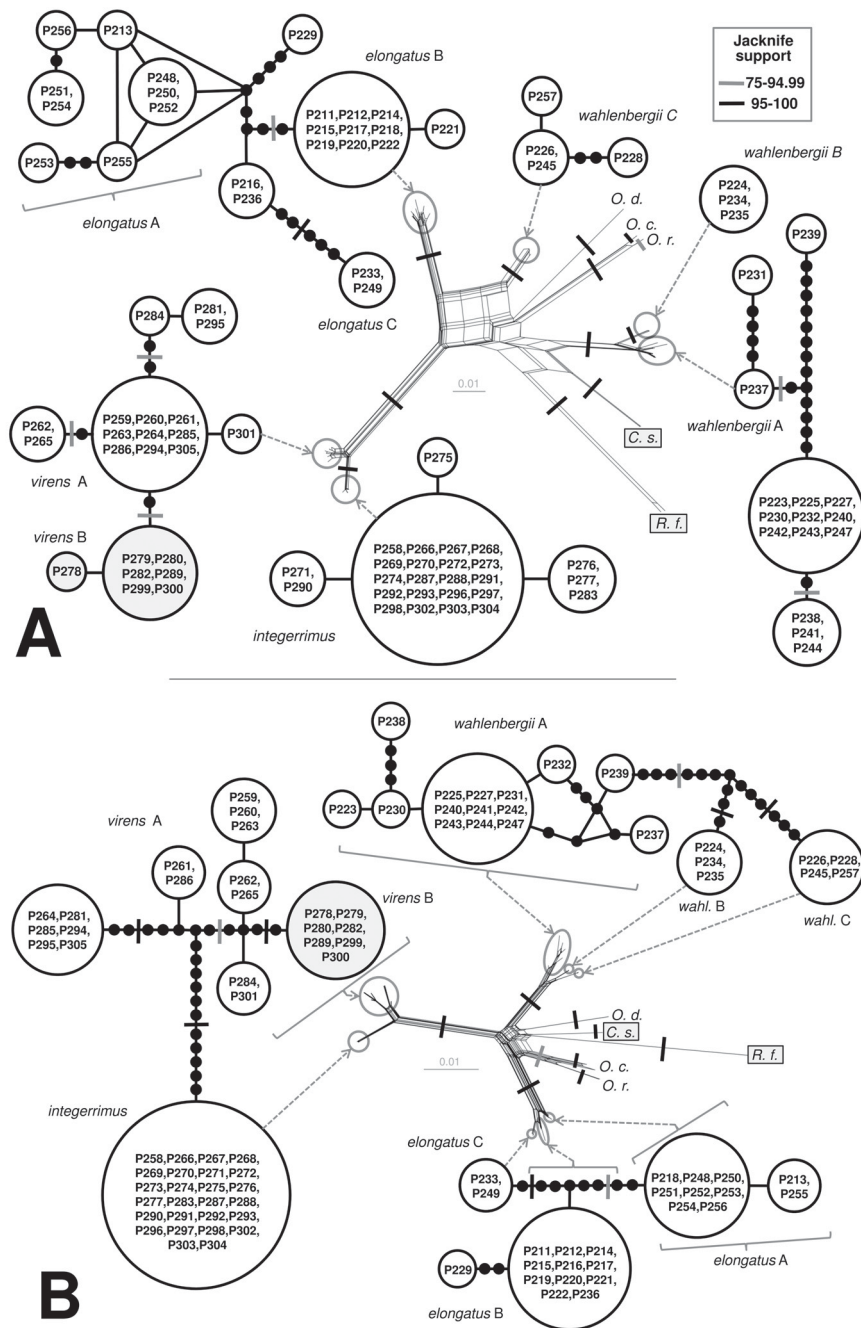

The NN split networks and the corresponding haplotype networks identified by TCS are shown with indications of branches having Jackknife support of at least 75 in Fig. 1. Both the nuclear and plastid data provide support for the three *O. elongatus* entities A–C, except that P218 belongs to B according to the ITS data and A in the plastid data. Support is provided for the three *O. wahlenbergii* entities A–C. Both data sets also support the two main entities *O. virens* and *O. integerrimus* (sp. nov.; see below) in *O. virens* s. lat., with additional differentiation within *O. virens* s. str., although the latter is incongruent between the two data sets except for *O. virens* B, that differs from *O. virens* A in 2 (ITS) or 3 mutations (Fig. 1).

### *Morphological evaluation*

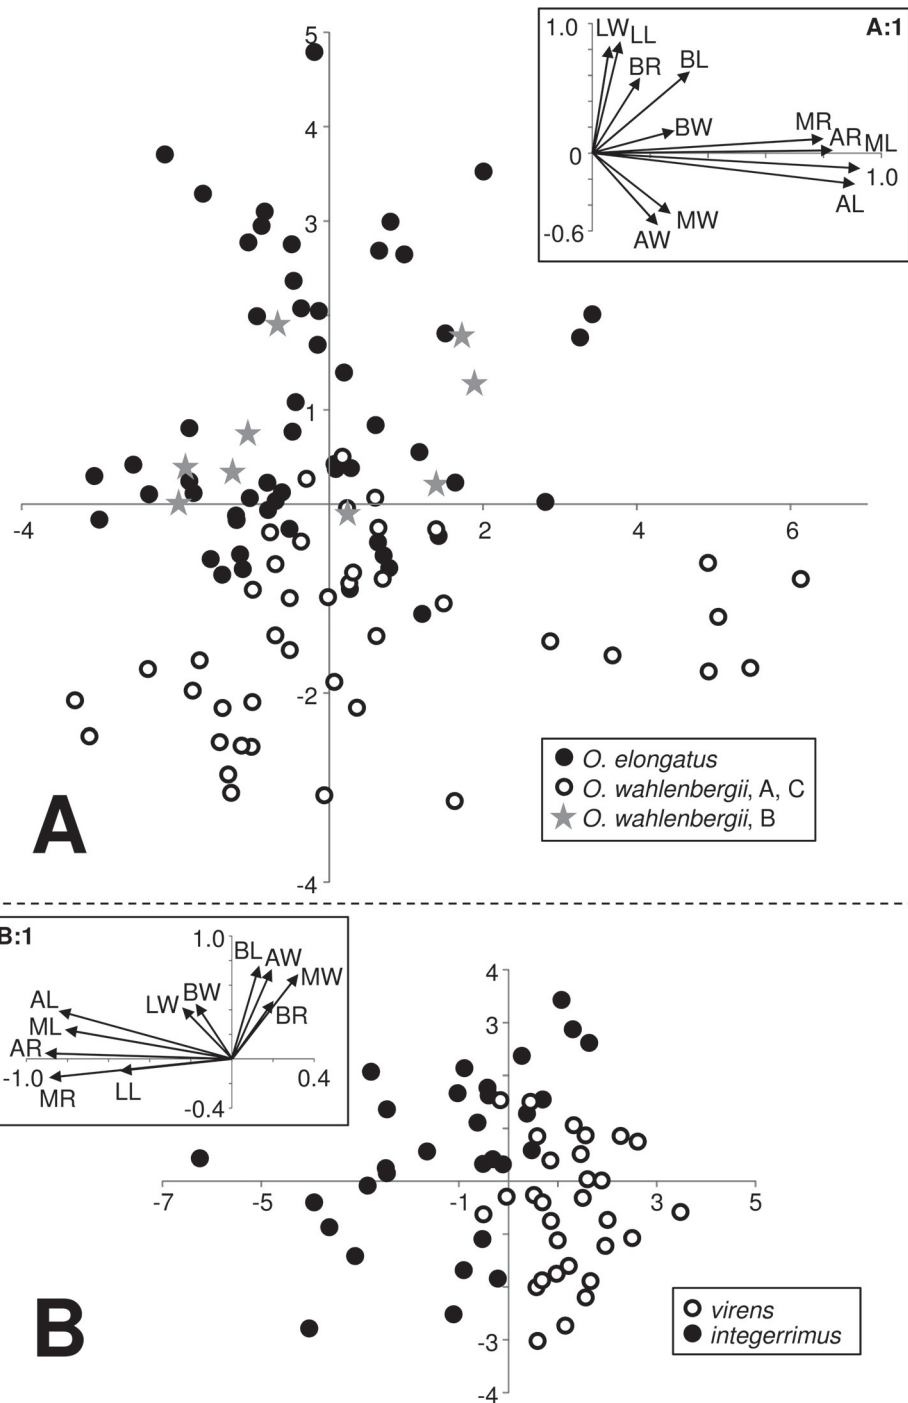

No differences could be found between *O. wahlenbergii* A and C (not shown), and these are therefore merged in the following (*O. wahlenbergii* AC). The PCA based on leaf and leaf cell measurements revealed that *O. elongatus* differs from *O. wahlenbergii* AC, with some overlap between the two (Fig. 2A). The differentiation is along PCA axis 2, showing that leaf length and width, as well as the width of cells in the apical and middle portions of the leaves, are most important in explaining this separation (Fig. 2A:1). *Oncophorus elongatus* and *O. wahlenbergii* AC differ from each other in five out of nine individual leaf lamina cell sizes or length-to-width ratios, whereas *O. wahlenbergii* B is sometimes most similar to either *O. elongatus* or *O. wahlenbergii* AC, sometimes intermediate between these, or its mean values are larger or smaller than those of both the other two (Table 2; cf., Fig. 2A). Also *O. virens* and *O. integerrimus* sp. nov. differ from each other in the PCA based on these parameters, again with a small overlap (Fig. 2B). The main differentiation is along PCA axis 1, and leaf length, length of the apical leaf lamina cells and width of the middle ones, as well as the length-to-width ratio of the apical and middle lamina cells contribute most to this pattern (Fig. 2B:1). These two species differ in all cell measurements (Table 3). Finally, despite the found statistical differences, which are based on large numbers of measurements from molecularly identified groups, the overlap among *O. elongatus*-*O. wahlenbergii* entities and between *O. virens*-*O. integerrimus* sp. nov. in individual characters is large (Supplementary file: Figs S1, S2).

### *Geographical distribution and habitat*

The distribution of the four Scandinavian *Oncophorus* species is mapped in Fig. 3, based on the material in S. All species can grow in several habitat types, but each species is most commonly found in one or two of these (Fig. 4). Three members of the genus (*O. elongatus*, *O. wahlenbergii*, *O. integerrimus* sp. nov.)

**Fig. 1.** NeighborNet split network for the 104 specimens studied, based on ITS (**A**) and the chloroplast markers *trnG* and *rps4* (**B**): *Oncophorus crispifolius* (*O.c.*, 2 specimens), *O. dendrophilus* (*O.d.*, 2), *O. elongatus* (24), *O. rauei* (*O.r.*, 2), *O. virens* (22), *O. wahlenbergii* (22), *O. integerrimus* Hedenäs sp. nov. (26), and outgroup (light grey boxes: *C.s.* = *Cynodontium strumiferum*, 2; *R.f.* = *Rhabdoweisia fugax*, 2). Haplotype networks based on all samples of *O. elongatus*, *O. virens*, *O. wahlenbergii*, and *O. integerrimus* Hedenäs sp. nov. are shown distal to ‘branches’ identified in the split network to show the full resolution among haplotypes. Circle size in the haplotype networks is proportional to the number of sampled populations of a certain haplotype, and sample numbers are explained in Table 1. Circles connected by a line differ in a single mutational difference; black dots indicate ‘missing’ haplotypes. Jackknife support values of 75–94.99 and 95–100 are indicated by transverse grey and black lines, respectively.

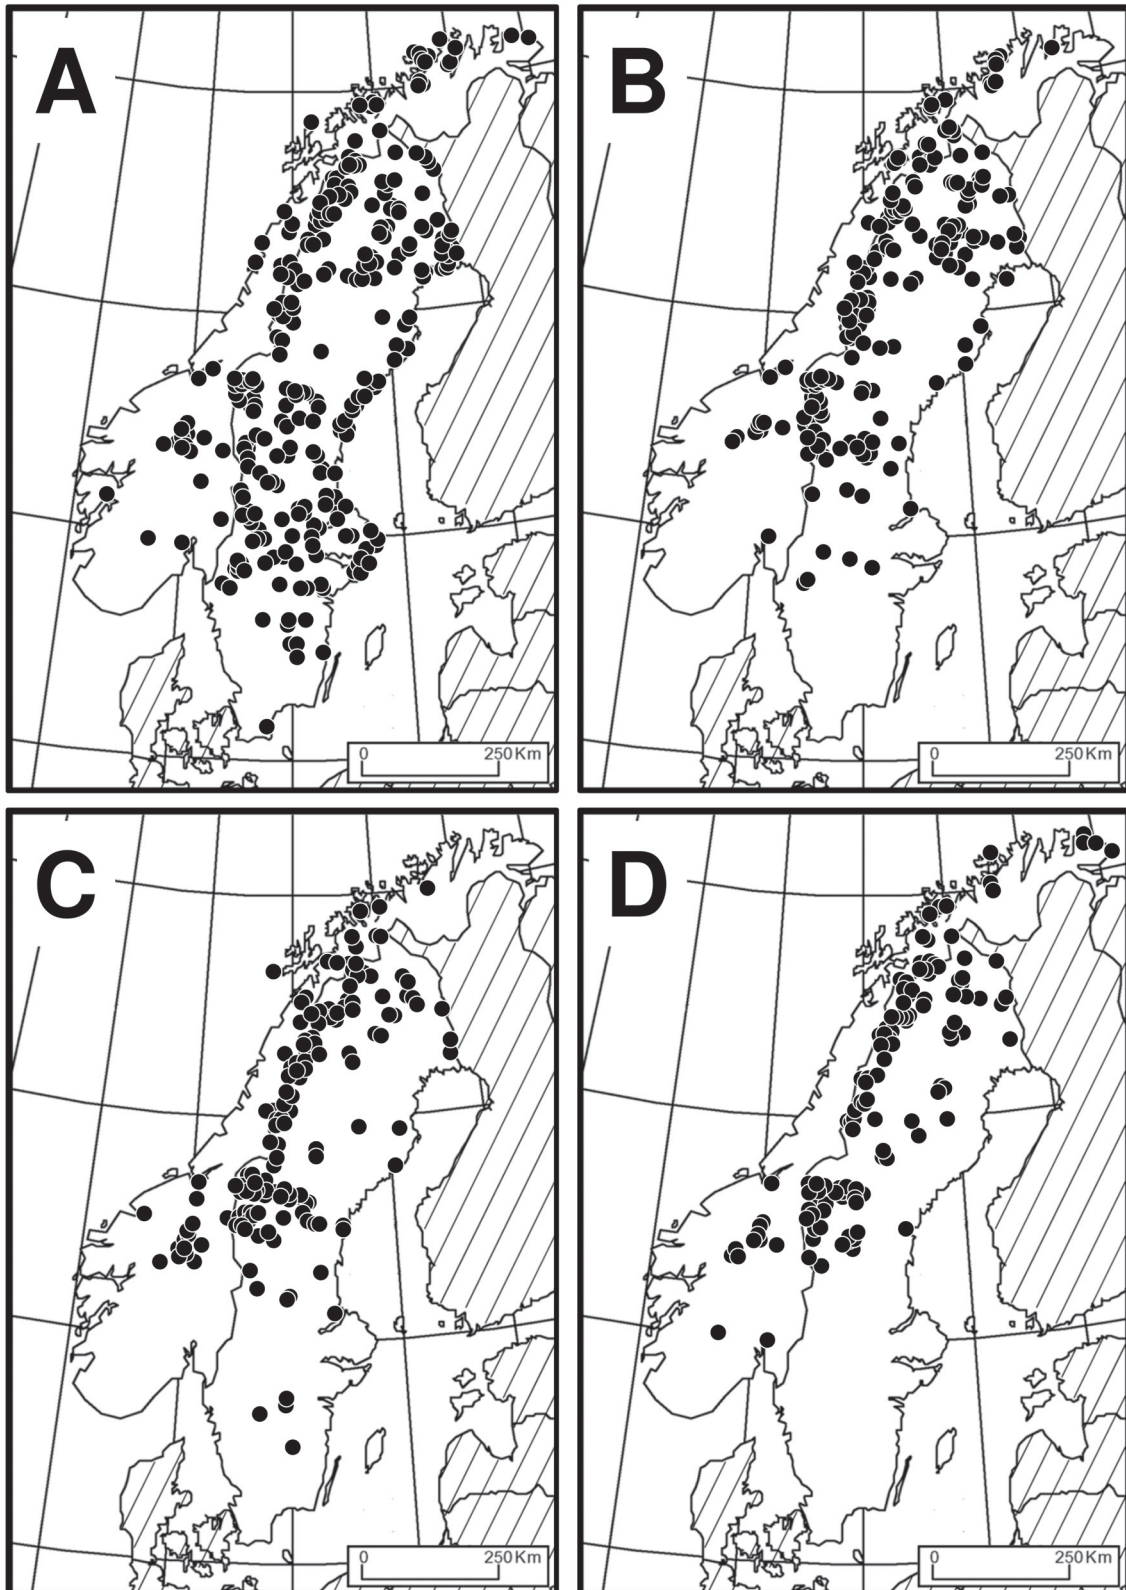

**Fig. 2.** The positions of three leaves from each of 18 molecularly identified specimens of *O. elongatus*, 14 of *O. wahlenbergii* A and C, and 3 of *O. wahlenbergii* B (cf. Fig. 1) (A), and of 10 specimens of *O. virens* and 10 of *O. integerrimus* Hedenäs sp. nov. (B), along the first two axes in a PCA. The PCA is based on each leaf's length (LL), width (LW), and leaf lamina cell length, width, and length/width ratio in the apical (AL, AW, AR), middle (ML, MW, MR), and sheathing basal (BL, BW, BR) lamina. Cell measurements are the mean values of 20 cells per position in each leaf. Axes 1 (x) and 2 (y) explain 30.69% and 25.24% of the variation in A, and 32.56% and 22.01% of the variation in B. Insert diagrams **A:1** and **B:1** depict explanatory factors in the plane of these two axes.

**Table 2.** Means plus standard errors for cell measurements in the acumen (20 cells per leaf), in mid-leaf (20), and in the sheathing base (20) from three leaves in each of 18 specimens of *Oncophorus elongatus*, three specimens of *O. wahlenbergii* B, and 14 specimens of *O. wahlenbergii* A and C (AC). The number of measured cells at each position, n, is indicated after the species. Significant pair-wise differences between species revealed by the Kruskal-Wallis test are indicated by different letters appended after the values in the respective columns, for the Bonferroni corrected p values corresponding with  $p < 0.05$ .

**Fig. 3.** Geographical distributions in Scandinavia. **A.** *Oncophorus elongatus* (n = 459). **B.** *O. wahlenbergii* (n = 333). **C.** *O. virens* (n = 361). **D.** *O. integerrimus* Hedenäs sp. nov. (n = 247). The distribution maps are based on the S material for which geographical origin could be determined.

**Fig. 4.** Habitat preferences of *Oncophorus elongatus*, *O. wahlenbergii*, *O. virens*, and *O. integerrimus* Hedenäs sp. nov. in Scandinavia, based on label information from studied material in S.

**Fig. 5. A.** Latitudinal and longitudinal distribution of *Oncophorus elongatus* samples belonging to different haplotypes or groups of haplotypes (cf., Fig. 1) based on ITS and plastid (*trnG*, *rps4*) data. Sample P218 is related to *O. elongatus* B according to ITS data and *O. elongatus* A according to plastid data (Fig. 1). The positions of the Swedish towns Kiruna (K), Stockholm (St), Sundsvall (Su), and Östersund (Ö) are indicated as references. **B.** Elevational distribution of the molecularly sampled *Oncophorus virens* A and B (P278-P280, P282, P289, P299, P300) in Scandinavia.

have between 40 and 55% of their recorded occurrences in fens, springs, wet meadows and similar habitats. In addition, 35% of the finds of *O. elongatus* are from decomposing wood, an unimportant habitat for the other species, and for *O. wahlenbergii* and *O. integerrimus* sp. nov. 20–25% of the records are from shores of brooks and lakes, wet rocks, and similar habitats. Shores and wet rocks are the most important habitats for *O. virens*, which has more than 45% of its records there. This species is the only one with a significant number of occurrences in late snow-beds.

Within *O. elongatus*, the molecular differentiation corresponds with a geographic pattern. Samples from the lowlands and along the Bothnian coast mostly belong to *O. elongatus* A, whereas samples from the mountain range and the Norwegian coast are predominantly *O. elongatus* B (Fig. 5A). No such geographic pattern was found within the other species. Within *O. virens*, on the other hand, we find a very clear differentiation between low (*O. virens* A) and high (B) elevation haplotypes (Fig. 5B).

### **Key to Scandinavian *Oncophorus* species**

1. Stem leaf margin plane throughout; alar cells not or weakly differentiated from other basal cells ...2
  - Stem leaf margin at least partly distinctly recurved in lower leaf; alar cells well differentiated .....3
  
2. Lamina of basal, sheathing leaf portion in its middle and lower portions with long and narrow cells along margin; margin and often back of costa in upper (10–)25–35(–50)% of many leaves denticulate or dentate, often sharply so, rarely with only a few leaves having scattered obtuse teeth above. Vegetative leaves 2.5–6.4 × 0.4–1.2 mm .....1. ***O. elongatus*** (I.Hagen) Hedenäs
  - Lamina of basal, sheathing leaf portion with quadrate to elongate-rectangular cells extending down along margin (from spreading lamina); margin and back of costa smooth, with an occasional and mostly obtuse and irregular denticle (mostly close to leaf apex), or sometimes with projecting cell walls. Vegetative leaves 1.4–4.4 × 0.3–0.8 mm .....2. ***O. wahlenbergii*** Brid.
  
3. Leaf margin in acumen and often down to mid-leaf regularly to irregularly dentate or coarsely denticulate with mostly sharp and often some double teeth, strong teeth often directed forwards, occasional leaves less distinctly dentate. Dry leaves with acumen from above sheathing base erect and tightly incurved to spreading, above strongly twisted .....3. ***O. virens*** (Hedw.) Brid.
  - Leaf margin in acumen entire or indistinctly and obtusely denticulate, occasionally distinctly denticulate close to leaf apex. Dry leaves with acumen from above sheathing base erect-patent to spreading and loosely incurved or curved upwards, upper acumen loosely but relatively strongly twisted .....4. ***O. integerrimus*** Hedenäs sp. nov.

### **Taxonomy**

For all species, the total number of studied specimens is indicated in Fig. 3, and a selection of studied specimens is found in Table 1.

Class Bryopsida Pax (Pax 1900)  
 Subclass Dicranidae Doweld (Doweld 2001)  
 Order Dicranales M.Fleisch. (Fleischer 1920)  
 Family Oncophoraceae M.Stech (Stech & Frey 2008)

Genus *Oncophorus* Brid. (von Bridel 1826)

*Bryologia Universa* 1: 389 (von Bridel 1826). – Type: *Oncophorus virens* (Hedw.) Brid.

1. *Oncophorus elongatus* (I.Hagen) Hedenäs

Fig. 6

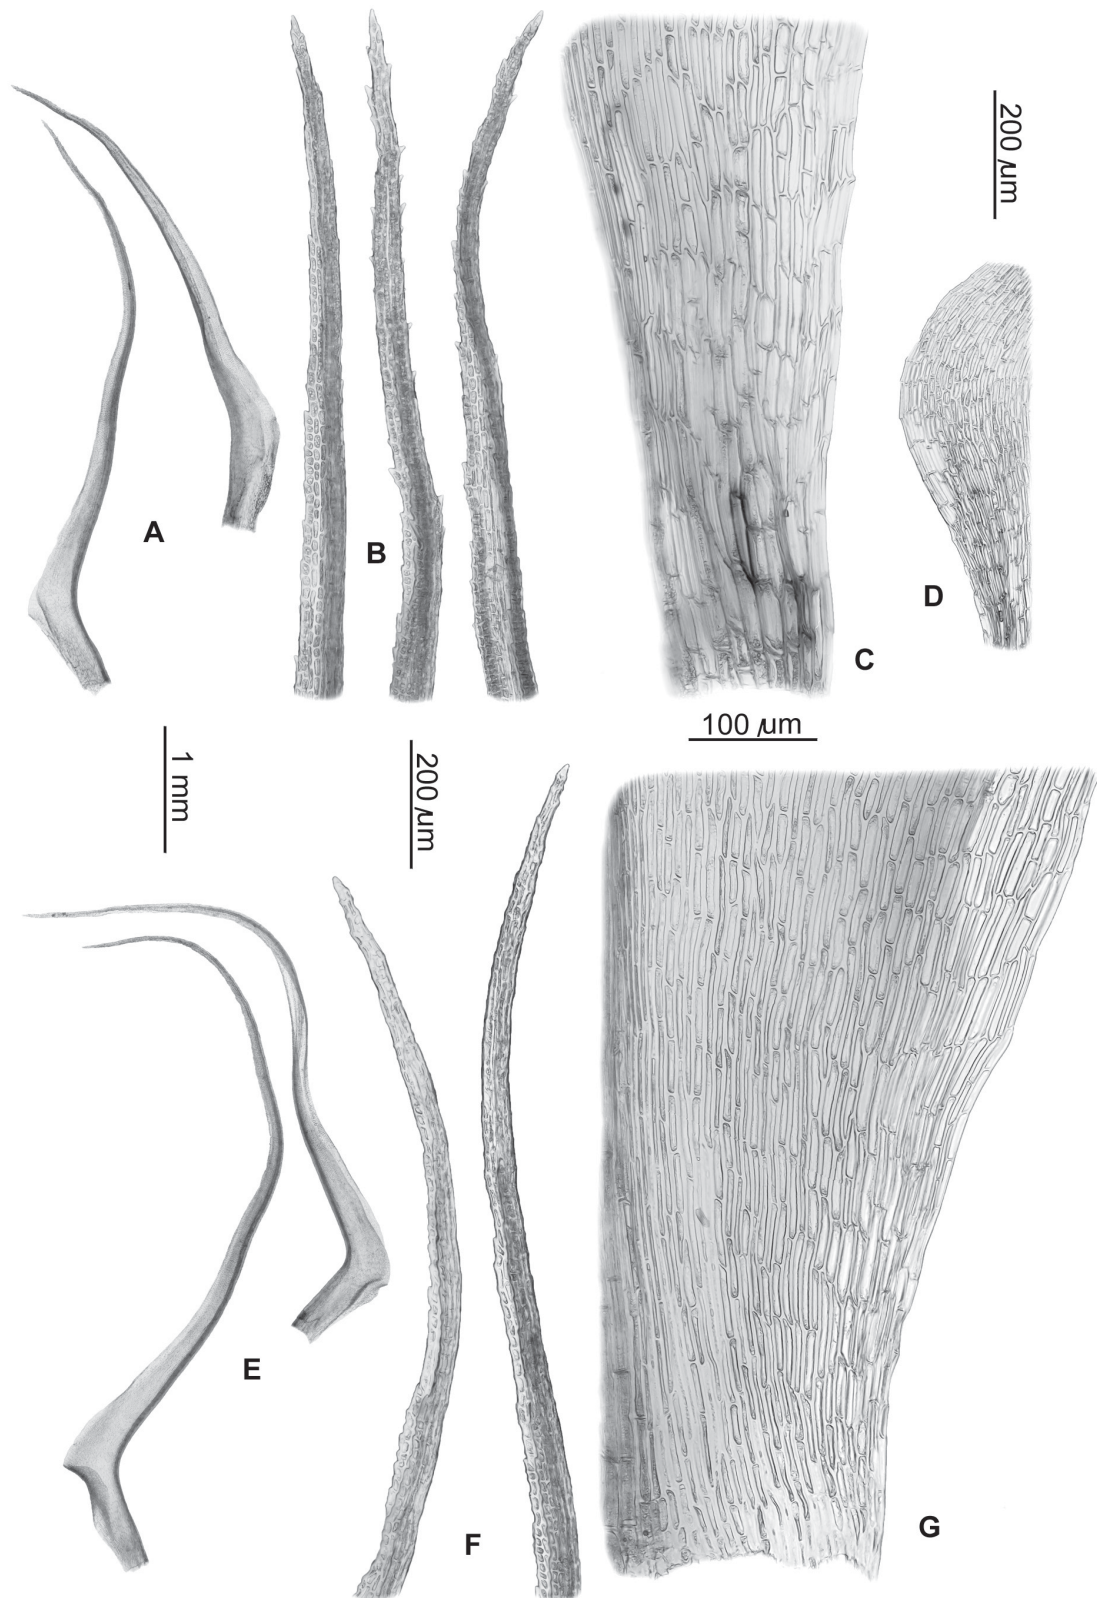

*Lindbergia* 30: 36 (Hedenäs 2005). – *Oncophorus wahlenbergii* var. *elongatus* I.Hagen, *Tromsø Museums Aarshefter* 21–22: 13 (Hagen 1899). – *Cynodontium wahlenbergii* var. *elongatum* (I.Hagen) Mönk., *Die Laubmoose Europas*: 195 (Mönkemeyer 1927). – Type: “Norway. Nordland, Saltdalen, Rognanfjeld, 67° 6' N, 600 m asl, 21 July 1889, R. E. Fridtz” (lecto-: O!, designated by Hedenäs 2005).

**Description**

Plants up to ten cm high, mostly in loose tufts, green or yellow-green. Stem with large central strand, a cortex plus epidermis of 1–2 layers of incrassate cells, epidermis not differentiated as a hyalodermis; axillary hairs with 2–8-celled, hyaline upper portion, 8–10  $\mu\text{m}$  wide, basal 1–2 cells rectangular, brown; rhizoids strongly branched, red-brown, smooth, in leaf axils or shortly above. Leaves 2.5–6.4  $\times$  0.4–1.2 mm, when moist from strongly sheathing base erect, or erect-patent to spreading and straight or slightly curved, when dry with middle leaf spreading and gradually curved upwards or upwards-inwards and curled or slightly curled, from oblong-obovate or ovate sheathing portion (narrowed or strongly narrowed towards insertion) with long and almost linear, gradually narrowing upper portion, apex long- or very long-acuminate; leaf margin plane throughout, below entire, in upper 20–25(–35)% partly irregularly dentate or denticulate with sharp forwards-directed teeth, or sometimes relatively weakly denticulate, or some leaves almost entire and other leaves with scattered teeth along upper margin, teeth single or occasionally double, sometimes with cell walls projecting along upper margin, margin varying from unistratose to bistratose; costa 53–125  $\mu\text{m}$  wide near base, with dorsal and ventral epidermis cells slightly widened but incrassate, one layer of large guide cells, 1–3 layers of ventral stereids and 2–3(–4) layers of dorsal stereids, sometimes with mammillae, or erect to forwards-directed teeth on upper back; lamina cells in acumen incrassate or strongly so, 10–21  $\times$  9–14  $\mu\text{m}$ , 0.9–2.0 times as long as wide, in mid-leaf incrassate or strongly so, 11–29  $\times$  8–13  $\mu\text{m}$ , 1–3 times as long as wide, and in sheathing lamina strongly incrassate and eporose or indistinctly porose, 36–88  $\times$  8–14  $\mu\text{m}$ , 3.5–9.1 times as long as wide, transition between mid-leaf and basal cells gradual, due to relatively long mid-leaf cells and relatively short basal cells, lamina of basal, sheathing portion of leaf in middle and below with long and narrow cells also along margin; alar cells undifferentiated or a few cells slightly wider than other basal cells and sometimes brownish, unistratose, not or shortly and narrowly decurrent. Perigonia lateral on stem, not or shortly stalked, antheridia protected by oblong-triangular perigonial leaves having obtuse to narrowly acuminate acumen. Inner perichaetial leaves 5.36–7.14 mm long, lower 26–42% oblong and broadly sheathing, above suddenly narrowed to long, narrow acumen. Seta tall, (6–)12–25 mm; capsule obloid, slightly curved, with distinct struma, 0.9–1.4  $\times$  0.5–1.0 mm, 1.3–2.1 times as long as broad, more or less orthogonal; exothecial cells slightly incrassate, mostly slightly collenchymatous; stomata ovate-pored, surrounded by indistinctly radially arranged cells, near base of capsule; peristome orange-red, teeth cleft or perforated to one- or two-thirds down, with longitudinal rows of pits on outside; spores 23–30  $\mu\text{m}$ , very finely rough.

**Remarks**

Well-developed *O. elongatus* has very long leaves, which are narrow above their sheathing base. In oceanic portions of the Scandinavian mountain range and along the Norwegian coast the species often grows in open fens or wet heaths or meadows and then the leaves are mostly spreading and give the plants a very characteristic appearance. This is the kind of plants that made Hagen (1899) distinguish *O. wahlenbergii* var. *elongatus* and Hedenäs (2005) raise it to the species level. However, molecular data show that this species is variable both molecularly and morphologically and with the present circumscription, the species includes also plants with different leaf orientations and from different habitats than the plants originally referred to it. Morphologically, this species differs from *O. wahlenbergii* in that the middle and basal portions of the basal, sheathing lamina have long and narrow cells also along its margin. In

**Fig. 6.** A–D. *Oncophorus elongatus* A (specimen P251; cf., Table 1). E–G. *O. elongatus* B (specimen P221, cf. Table 1). A, E. Stem leaves. B, F. Upper leaf acumen. C, G. Marginal and alar portions of sheathing leaf base (margin to the right). D. Portion of leaf at widest point, showing the flat margin.

addition, *O. elongatus* has longer vegetative leaves than *O. wahlenbergii*, and some or many leaves have almost always got denticulate or sharply denticulate upper margins, often with denticles on the back of the costa also. Rarely some plants have only a few leaves with denticles along the margin, and their denticles are in addition scattered and obtuse. In such cases the cell pattern of the sheathing lamina can be used to distinguish the two species. As noted by Hedenäs (2005) the spore capsules of *O. elongatus* mature somewhat before those of *O. wahlenbergii*.

### Habitat and distribution in Scandinavia

This species is most frequent in open wetlands and humid forests, where it is found on humus-rich substrates and decomposing wood (Fig. 4). It occurs also on rocks, wet rocks, and on shores. *Oncophorus elongatus* is the most frequent and widespread member of the genus in Scandinavia (Fig. 3A), and is the only member of the genus that is relatively frequent also in large portions of the southern third of Sweden.

Garrett & W. Lillie, Aug. 1924, Comm. D. Lillie (Herb. H. N. Dixon Ref. No. 1138)” (holo-: BM, n.v. – synonymized by Frahm *et al.* 1998).

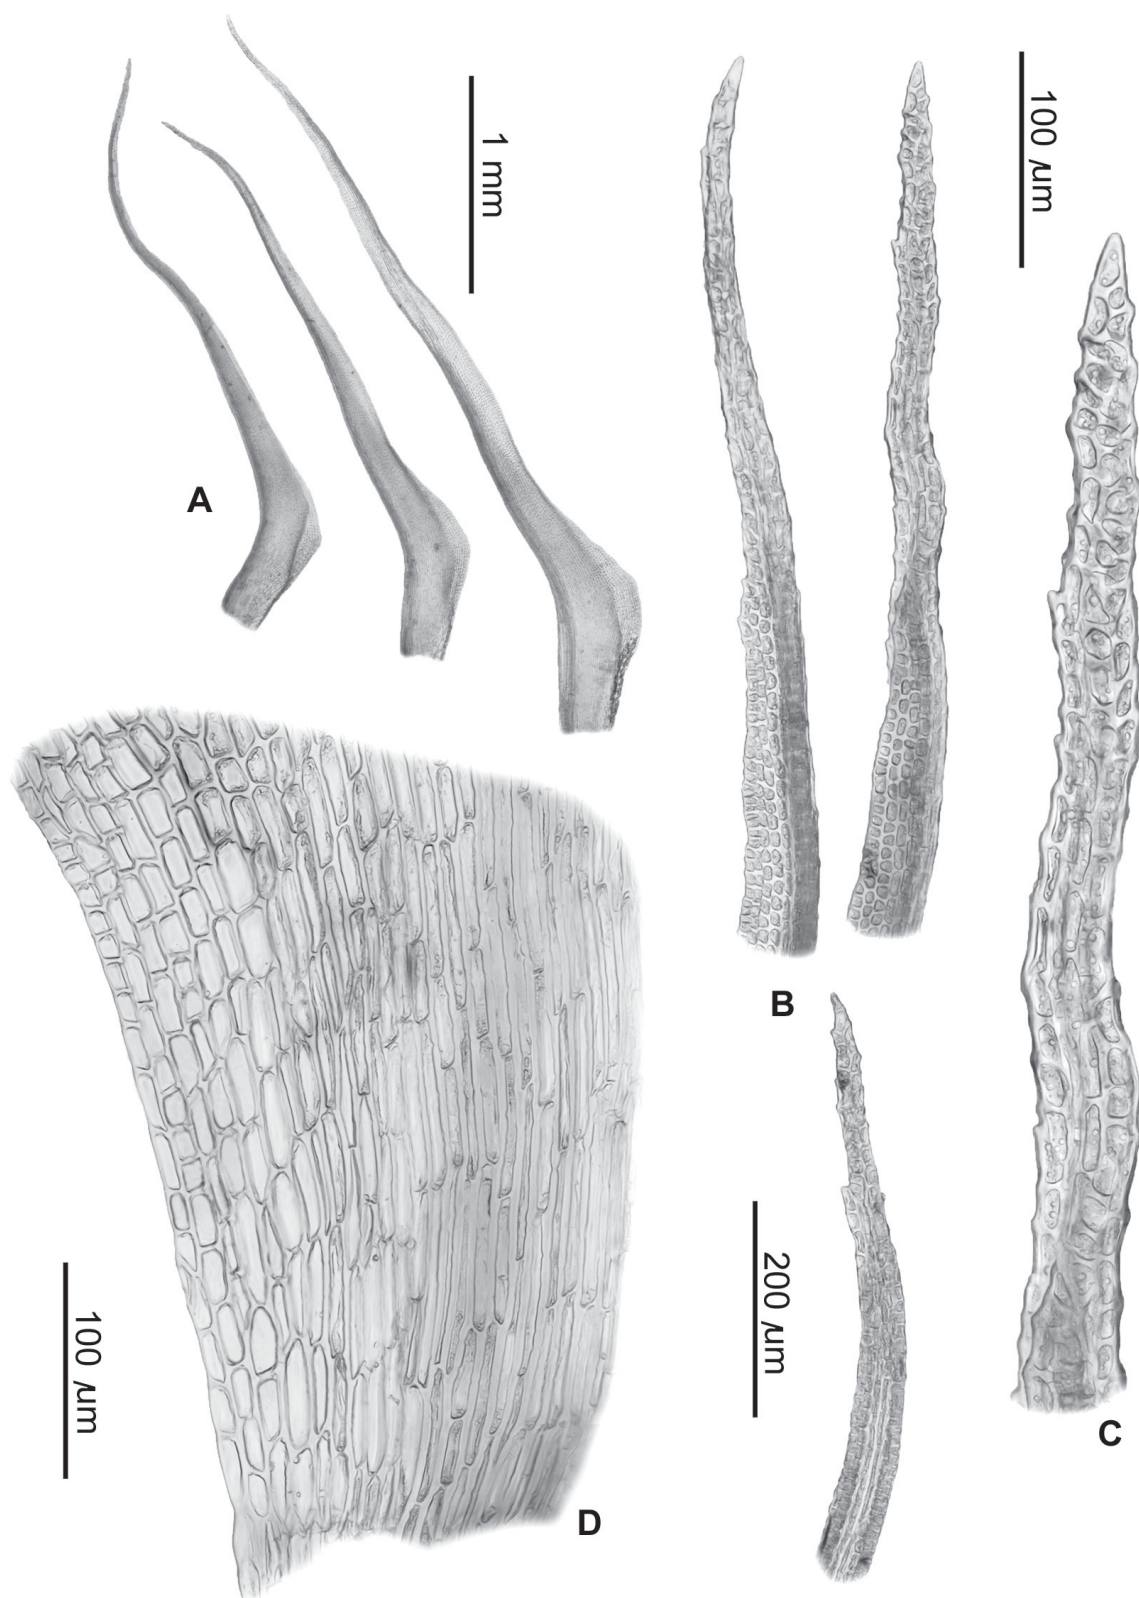

### Description

Plants from a few mm to several cm high, in loose tufts or dense cushions, green or yellow-green. Stem with large central strand, a cortex plus epidermis of 1–2 layers of incrassate cells, epidermis not differentiated as a hyalodermis; axillary hairs with (1–)2–4-celled, hyaline upper portion, 7–12 µm wide, basal 1–2 cells rectangular, hyaline or pale brown; rhizoids strongly branched, red-brown,

smooth, in leaf axils or shortly above. Leaves  $1.4\text{--}4.4 \times 0.3\text{--}0.8$  mm, when moist from sheathing base erect to spreading and straight or slightly curved, when dry with middle leaf spreading and gradually curved upwards-inwards and slightly curled or weakly curled, from oblong or slightly oblong-obovate sheathing portion (narrowed towards insertion) with narrowly triangular to almost linear upper portion, gradually narrowing upper portion, apex obtuse, acute, acuminate or narrowly acuminate; leaf margin plane throughout, below entire, above entire or with one or few occasional and indistinct, mostly obtuse teeth, especially close to leaf apex, sometimes with cell walls distinctly projecting along upper margin, margin varying from unistratose to bistratose; costa  $31\text{--}88$   $\mu\text{m}$  wide near base, with dorsal and ventral epidermis cells slightly widened but incrassate, one layer of large guide cells, 1–2 layers of ventral stereids and 1–3 layers of dorsal stereids, sometimes with projecting cell walls or cell portions in upper costa; lamina cells in acumen incrassate,  $10\text{--}33 \times 10\text{--}15$   $\mu\text{m}$ , 0.9–2.4 times as long as wide, in mid-leaf

**Fig. 7.** *Oncophorus wahlenbergii* A (specimen P225; cf., Table 1). **A.** Stem leaves. **B.** Upper leaf acumen. **C.** Portion of leaf at widest point, showing the flat margin. **D, E.** Sheathing leaf portions, showing short marginal leaf cells (margin to the right) and, in D, alar region.

**Fig. 8.** *Oncophorus wahlenbergii* B (specimen P234; cf., Table 1). **A.** Stem leaves. **B.** Upper leaf acumen. **C.** Uppermost leaf acumen at higher magnification. **D.** Sheathing leaf portion, showing short marginal leaf cells and alar region (margin to the left).

incrassate,  $10\text{--}33 \times 8\text{--}17 \mu\text{m}$ , 0.9–3.0 times as long as wide, and in sheathing lamina strongly incrassate and eporose or indistinctly porose,  $30\text{--}72 \times 7\text{--}15 \mu\text{m}$ , 3.4–8.3 times as long as wide, transition between mid-leaf and basal cells gradual, due to relatively long mid-leaf cells and relatively short basal cells, lamina of basal, sheathing portion of leaf with quadrate or rectangular cells extending down along margin from spreading lamina; alar cells undifferentiated or a few cells wider than other basal cells, unistratose, not or shortly and narrowly decurrent. Perigonia lateral on stem, not or shortly stalked, antheridia protected by oblong-triangular perigonial leaves with obtuse or acute apex. Inner perichaetial leaves 2.73–4.24 mm long, lower 34–67% oblong and broadly sheathing, above suddenly narrowed to long, narrow acumen. Seta tall, 9–22 mm; capsule obloid, curved or slightly curved, with distinct struma,  $0.5\text{--}1.3 \times 0.3\text{--}0.7 \text{ mm}$ , 1.2–2.5 times as long as broad, more or less orthogonal; exothecial cells incrassate, sometimes more strongly so in longitudinal walls, not or weakly collenchymatous; stomata sparse, ovate-pored or lacking pore, surrounded by radially arranged cells, near base of capsule; peristome red, teeth cleft or perforated to one-fourth or further down, with longitudinal rows of pits on outside; spores  $21\text{--}29\text{--}(32) \mu\text{m}$ , finely rough.

### Remarks

*Oncophorus wahlenbergii* is the smallest Scandinavian species. Contrary to *O. elongatus* it has quadrate or rectangular marginal cells in the middle and basal portions of the basal, sheathing lamina. In addition, its vegetative leaves are shorter than in *O. elongatus*, and in their upper portions the margins are entire or have occasionally one or a few indistinct teeth, especially close to the leaf apex. In some plants the cell walls project distinctly along the upper margin, and sometimes on the uppermost back of the costa.

### Habitat and distribution in Scandinavia

*Oncophorus wahlenbergii* is most often found in open wetlands, but occurs also on soil, rocks, wet rocks, and on shores (Fig. 4). The species is widespread, but compared with *O. elongatus* it is much less common outside the mountain range and the far north (Fig. 3B), and has only been collected a few times in the southern third of Sweden.

### Nomenclatural notes

The isotype of *Oncophorus sardous* Herzog (Herzog 1910) in S has plane leaf margins and no or few marginal teeth near the leaf apex, and several rows of short cells along the leaf margin in the sheathing lamina. Despite an earlier synonymisation with *O. virens* Hedw. (Frahm *et al.* 1998), the material unambiguously belongs to *O. wahlenbergii* Brid. The partly mammillose apical costa back and few marginal teeth or projecting cell walls remind about the molecularly identified *O. wahlenbergii* B (Fig. 1). However, since the geographical origin of the *O. sardous* type is distant from Scandinavia, further information is required to confidently judge its relationship with other *O. wahlenbergii* specimens.

The protologue of *Oncophorus gracillimus* Dixon (Dixon 1926) mentions entire or almost entire leaf margins, which indicates that the synonymy with *O. wahlenbergii* suggested by Frahm *et al.* (1998) is correct.

Giraldi, determ. Dr. C. Müller n. 1970” (lecto-: BM-000517728!, designated here).

## Description

Plants up to 8 cm high, usually in loose tufts, green or yellow-green. Stem with large central strand, a cortex plus epidermis of 1–2 layers of incrassate cells, epidermis not differentiated as a hyalodermis; axillary hairs with 2–4-celled, hyaline upper portion, 10–11 µm wide, basal 1–2 cells rectangular, hyaline; rhizoids strongly branched, red-brown, smooth, in leaf axils. Leaves 2.1–4.2 × 0.6–1.0 mm, when moist from sheathing base patent to spreading, straight or screwed, when dry above sheathing base erect and tightly incurved to spreading, above strongly twisted, from ovate or rounded oblong base with narrowly triangular acumen, apex acuminate to longly acuminate; leaf margin at least partly distinctly recurved in lower leaf, below entire, upper margin in all or many leaves regularly to irregularly dentate or coarsely and somewhat irregularly denticulate, sometimes only close to leaf apex but mostly in at least some leaves down to mid-leaf or almost so, teeth single or double, mostly sharp and when strong often directed forwards, margin varying from unistratose to bistratose; costa 83–120 µm wide near base, with dorsal and ventral epidermis, one layer of large guide cells, 1(–2) layers of ventral stereids and 2–3 layers of dorsal stereids; lamina cells in acumen incrassate, 6–30 × 6–18 µm, 0.5–3.3 times as long as wide, in mid-leaf incrassate, 6–33 × 6–15 µm, 0.6–3.8(–4.2) times as long as wide, and in sheathing lamina incrassate and slightly porose, 20–109 × 5–19 µm, 1.6–15.8 times as long as wide, transition between mid-leaf and basal cells relatively sudden, due to relatively short upper lamina cells and relatively long basal cells; alar cells differentiated, rectangular, slightly to strongly inflated and forming a diffusely delimited group of 3–4 cells wide and 2–4(–5) cells long, partly bistratose, decurrent. Perigonia lateral on stem, not stalked, antheridia protected by oblong perigonial leaves with “cut-off” or acute apex. Inner perichaetial leaves 3.27–6.18 mm long, lower 29–50% oblong and broadly sheathing, above suddenly narrowed to long, narrow acumen. Seta tall, 12–29 mm; capsule cylindric or shortly so, curved or slightly curved, with distinct struma, 0.9–1.5 × 0.5–0.6 mm, 1.6–2.9 times as long as broad, more or less orthogonal to homotropus; exothecial cells incrassate or longitudinally incrassate, slightly collenchymatous or not; stomata ovate-pored, surrounded by radially arranged cells, near base of capsule; peristome red, teeth cleft or perforated to one-third or further down, with longitudinal rows of pits on outside; spores 23–38 µm, very finely rough.

### Remarks

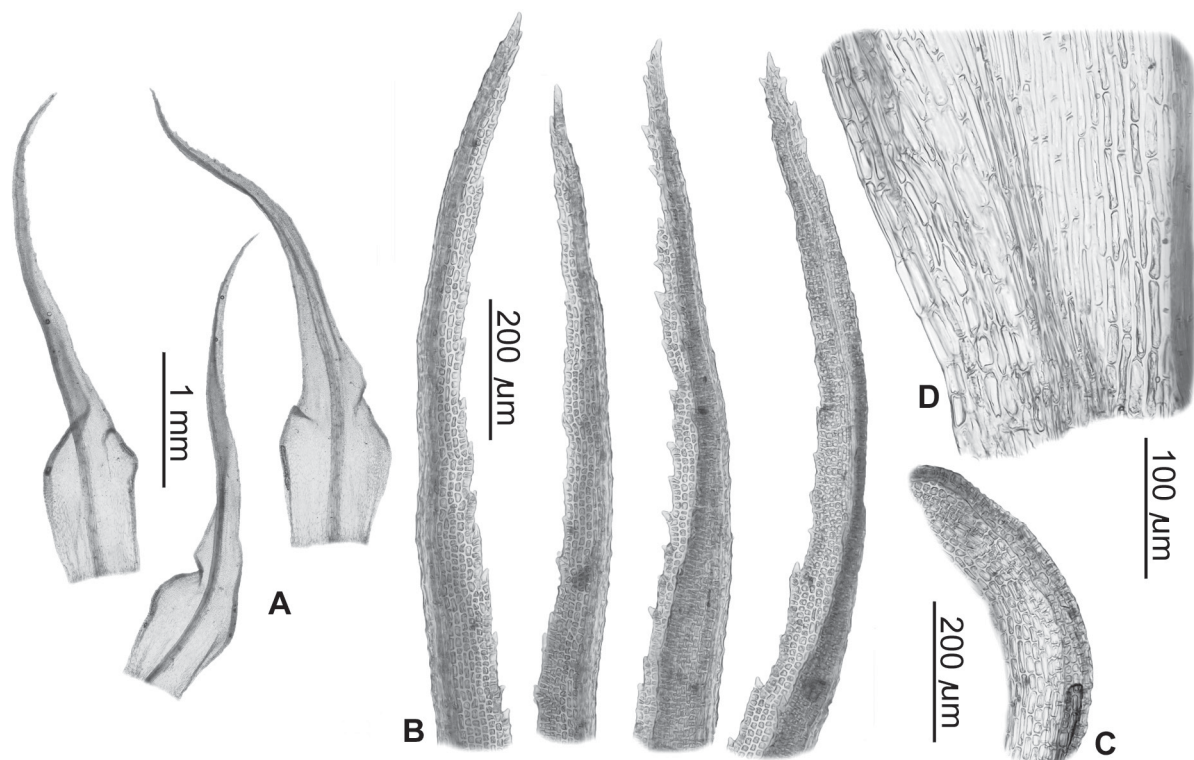

This species is on the average weaker than *O. integerrimus* sp. nov. In addition, it differs by its usually strongly dentate leaf margins and in that dry leaves are more tightly incurved. Plants from high elevations, which can be molecularly differentiated from lowland ones, are often relatively small. However, neither this nor other morphological features consistently distinguish plants from different elevations.

### Habitat and distribution in Scandinavia

*Oncophorus virens* occurs on rocks, especially wet rocks, and on brook and lake shores (Fig. 4). It is the only member of *Oncophorus* that is frequent in late snow-beds, and it grows also on soil and in open wetlands. This species is frequent mainly in the mountain range and the base- or calcium-rich lowland regions of northern Sweden (Fig. 3C). Like *O. wahlenbergii*, it has only been collected a few times in the southern third of Sweden.

### Nomenclatural notes

*Dicranum virens* var. *serratum* Bruch & Schimper. (Bruch & Schimper 1847) should differ from *Oncophorus virens* (Hedw.) Brid. var. *virens* in having strongly serrate leaf margins (Bruch *et al.* 1836–1851). However, since *O. virens* has serrate to strongly serrate upper leaf margins, the var. *serratus* belongs within this variation (cf., Ignatov & Afonina 1992; Newmaster 2007). The types of *Aongstroemia curvicaulis* Müll.Hal. (Müller 1898) and *Cynodontium bicolor* Paris (Paris 1900) also have strongly serrate leaf margins and clearly belong to *O. virens* as this species is understood here. The types of latter two names were checked to exclude that they belong to the next species.

**Fig. 9.** *Oncophorus virens* (specimen P286; cf., Table 1). **A.** Stem leaves. **B.** Upper leaf acumen. **C.** Portion of leaf at widest point, showing the broadly recurved margin. **D.** Lower part of sheathing leaf portion, showing differentiated alar region (margin to the left).

4. *Oncophorus integerrimus* Hedenäs sp. nov.

Fig. 10

*Oncophorus virens* var. *elongatus* Limpr., *Die Laubmoose Deutschlands, Oesterreichs und der Schweiz* 1: 309 (Limpricht 1886). – *Cynodontium virens* var. *elongatum* (Limpr.) Mönk., *Die Laubmoose Europas*: 195 (Mönkemeyer 1927). – Type: “An Quellen bei Innervillgraten in Tirol (Gander) und im Valée d’Eyne in den Pyrenäen 200 m (Renauld)” (syn-: BP, n.v.).

**Diagnosis**

*Oncophorus integerrimus* sp. nov. differs from *O. virens* (Hedw.) Brid. by its more loosely incurved leaves when dry, and in having entire or almost entire upper leaf margins.

**Etymology**

The epithet ‘*integerrimus*’ refers to the mostly entire leaf margin.

**Type material**

SWEDEN: Härjedalen, Tännäs, SW slope of Mt. Joltère (Lill-Mittåkläppen), 960 m a.s.l., periodically wet depression at margin of fen, 2 Sep. 2014, *Lars Hedenäs s.n.* (holo-: S, B207536!; iso-: BM!, NY!).

**Description**

Plants up to ten cm high, usually in loose tufts, green or yellow-green. Stem with large central strand, a cortex of (0–)1–3 layers of strongly incrassate cells, and an epidermis of one layer of thin-walled or slightly incrassate cells, sometimes partly differentiated as a hyalodermis; axillary hairs with 2–8-celled, hyaline upper portion, 8–12 µm wide, basal 1–2 cells rectangular, hyaline; rhizoids strongly branched, red-brown, smooth, in leaf axils. Leaves 2.7–5.0 × 0.6–1.1 mm, when moist from sheathing base erect-patent to spreading, straight or screwed, when dry loosely incurved and curled or twisted, from ovate or rounded-oblong base with longly and narrowly triangular acumen, apex longly acuminate; leaf margin at least partly distinctly recurved in lower leaf, below entire, in upper leaf mostly entire or indistinctly and obtusely denticulate, occasionally distinctly denticulate close to leaf apex, denticles single, margin varying from unistratose to bistratose; costa 75–146 µm wide near base, with dorsal and ventral epidermis, one layer of large guide cells, 1–4 layers of ventral stereids and 2–4 layers of dorsal stereids; lamina cells in acumen incrassate, 6–38(–49) × 5–15 µm, 0.6–4.5(–5.8) times as long as wide, in mid-leaf incrassate, 6–42 × 4–12 µm, 0.6–6.1(–7.2) times as long as wide, and in sheathing lamina slightly incrassate or incrassate and slightly porose, 16–91 × 5–22 µm, 1.4–12.4 times as long as wide, transition between mid-leaf and basal cells gradual, due to relatively long mid-leaf cells and relatively short basal cells; alar cells differentiated, rectangular, slightly to strongly inflated and forming a diffusely delimited group of 3–5 cells wide and 3–5(–6) cells long, partly bistratose, decurrent. Perigonia lateral on stem, not stalked, antheridia protected by oblong perigonial leaves with “cut-off” or acute apex. Inner perichaetial leaves 4.29–6.02 mm long, lower 32–58% oblong and broadly sheathing, above suddenly narrowed to long, narrow acumen. Seta tall, 18–27 mm; capsule cylindric, curved, with distinct struma, 1.3–1.8 × 0.5–0.8 mm, 1.8–2.6 times as long as broad, more or less orthogonal to homotropus; exothecial cells slightly incrassate or longitudinally incrassate, collenchymatous or not; stomata ovate-pored, surrounded by radially arranged cells, near base of capsule; peristome red, teeth cleft or perforated to middle or further down, with longitudinal rows of pits on outside; spores 18–28 µm, very finely rough.

**Remarks**

When well developed this is a large species, with on the average more longly and narrowly acuminate leaves than in *O. virens*. When dry, the leaves are loosely incurved or curved upwards, and the upper acumen is loosely but relatively strongly twisted. The leaf margin in the acumen is mostly entire, but

sometimes slightly uneven or has a few and usually low and irregular obtuse teeth. Occasionally one or a few sharp teeth may occur, especially close to the leaf apex.

### Habitat and distribution in Scandinavia

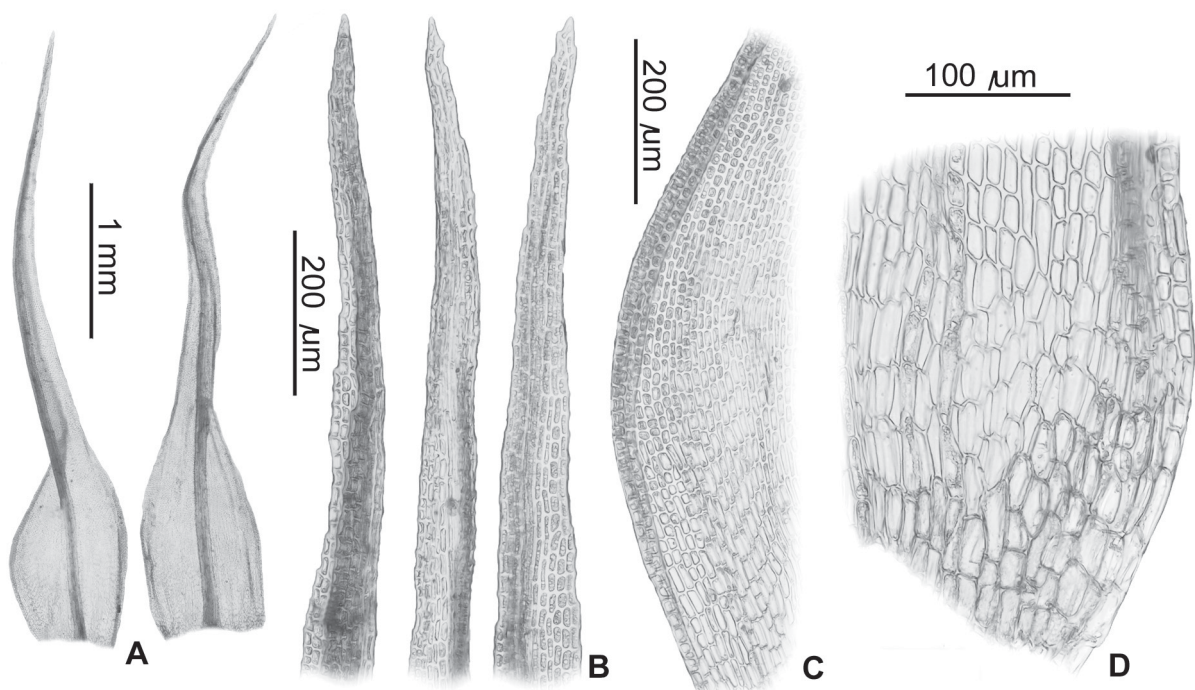

*Oncophorus integerrimus* sp. nov. is found most often in open wetlands, but occurs also on soil and wet rocks, often on shores (Fig. 4). The distribution of *O. integerrimus* sp. nov. is similar to that of *O. virens*, but geographically more restricted (Fig. 3D). Of the four Scandinavian *Oncophorus* species it is the only one that has not been found in southern Sweden, although there are few finds from southern Norway.

### Nomenclatural note

The synonymy of *Oncophorus virens* var. *elongatus* Limpr. is based on protologue information (Limpricht 1886) and on material collected by Gander at the type locality two years after the description of the taxon (S-B232585). The name of the variety cannot be used at the species level, since it is blocked by *Oncophorus elongatus* (I.Hagen) Hedenäs.

### Discussion

Although the monophyly of *Oncophorus* was not an issue in the present study, the positions of its species in relation to *Cynodontium strumiferum* and *Rhabdoweisia fugax* do not suggest otherwise. Neither in the ITS- nor chloroplast-based analyses, *O. crispifolius*, *O. dendrophilus*, and *O. rauei* were found in positions that suggested that they are especially closely related to any of the Scandinavian species. The molecular evidence presented here supports the recognition of the recently described *O. dendrophilus* (Hedderson & Blockeel 2006).

**Fig. 10.** *Oncophorus integerrimus* Hedenäs sp. nov. (holotype). **A.** Stem leaves. **B.** Upper leaf acumen. **C.** Portion of leaf at widest point, showing the broadly recurved margin. **D.** Lower part of sheathing leaf portion, showing differentiated alar region (margin to the right).

The molecular information available for Scandinavian *Oncophorus* suggests that species additional to the ones so-far accepted exist in the area. Four molecularly supported entities can also be distinguished based on their morphology, by a few qualitative characters, statistically significant differences in leaf cell measurements or on PCA scores based on these and leaf size. Four is therefore the minimum number of species to be recognized in the area. However, additional evolutionary lineages and in some cases most likely also biologically distinct cryptic species occur among the Scandinavian *Oncophorus*, considering the number of mutational differences between lineages as well as the lack of intermediates between these lineages. Cryptic species are here understood as lineages that are molecularly as distinct as those of the morphologically recognized species but which lack (known) morphological distinguishing features. For semi-cryptic species, weak quantitative morphological differentiation towards other molecularly identified entities is presently suggested by the data.

The two species *Oncophorus elongatus* and *O. wahlenbergii* are easily distinguished from *O. virens* and *O. integerrimus* sp. nov. by their plane rather than partially recurved leaf margins. *Oncophorus elongatus* differs from *O. wahlenbergii* in the shape of the marginal cells of the sheathing leaf portion, the denticulation or dentation of the upper leaf margins and costa, and overall leaf size, and except for *O. wahlenbergii* B in the quantitative leaf characters included in the PCA (Fig. 2A). Within *O. elongatus* one specimen shifted between *O. elongatus* A and B depending on whether ITS or chloroplast data were analysed. Such incongruence could be a result of several processes, such as incomplete lineage sorting or hybridization, but to determine the cause additional evidence is required (cf., Wendel & Doyle 1998; Harris 2008). On the other hand, there appears to be a phylogeographic signal distinguishing *O. elongatus* B as a western, oceanic or sub-oceanic entity that was mostly collected in fens and had usually got the long leaf portions above the sheathing base widely spreading, in contrast with the predominantly more eastern *O. elongatus* A that was mainly collected on dead wood or rocks and mostly presented less or not spreading leaves. Combined with the incomplete congruence between the two molecular data sets, this could be interpreted as two lineages that are still in the process of diverging. The distinct habit of *O. elongatus* B made Hedenäs (2005) believe that only this kind of plants belongs to *O. elongatus*, which is now shown to be incorrect. *Oncophorus elongatus* C is clearly distinct from *O. elongatus* A and B by 5–6 mutational changes according to both ITS and chloroplast data. Because only two of the sampled specimens belong to this lineage and no morphological feature was found that supports it, *O. elongatus* C is best treated as a potential cryptic species that requires further study.

Within *O. wahlenbergii* several well-supported molecular lineages that are differentiated by numerous mutations and have a high jackknife support exist. It seems likely that the three distinct lineages that are present in *O. wahlenbergii* represent cryptic species, or in the case of *O. wahlenbergii* B, which in some quantitative morphological traits overlaps more with *O. elongatus* than with *O. wahlenbergii* (Fig. 2A, Table 2), semi-cryptic species. The sampling of specimens from two of these three lineages occurred by pure chance, since neither *O. wahlenbergii* B nor C was clearly distinguishable by morphology alone. It is possible that a fuller sampling of *O. wahlenbergii* B, that allows comparing additional specimens with *O. wahlenbergii* A and C, would make it possible to refer at least a significant proportion of *O. wahlenbergii* B specimens to this lineage by morphology. According to ITS data, *O. wahlenbergii* C appears on another side of a major split than *O. wahlenbergii* A and B, *O. crispifolius*, *O. dendrophilus*, and *O. rauei*, which suggests that this lineage is more isolated than *O. wahlenbergii* B from *O. wahlenbergii* A, despite that *O. wahlenbergii* B is the one that may deviate morphologically from the latter.

*Oncophorus integerrimus* sp. nov. includes no jackknife-supported intraspecific variation. The leaf margins of *O. integerrimus* are entire, or occasionally denticulate near leaf apex, whereas *O. virens* has predominantly dentate or coarsely denticulate upper leaf margins; the species also differ in the quantitative leaf characters that were included in the PCA (Fig. 2B). *Oncophorus virens* displays intraspecific variation that is mainly incongruent between ITS and chloroplast data (cf., *O. elongatus*

above), except that *O. virens* B is distinct from *O. virens* A in both data sets. All seven specimens of *O. virens* B came from higher elevations than any of the 15 *O. virens* A specimens (Fig. 5B). This is highly unlikely as a chance result and therefore suggests that *O. virens* B is restricted to the cold climate of higher mountains. Since the temperature in the mountains is expected to increase with several degrees until the year 2100 (Berglöv *et al.* 2015a, 2015b; Nylén *et al.* 2015), it is urgent to examine the distribution of *O. virens* B and similarly distributed species and intraspecific entities in more detail. Organisms restricted to cold environments, such as *O. virens* B and the northern haplotypes of *Scorpidium cossonii* (Schimp.) Hedenäs (Hedenäs 1989) (Hedenäs 2009), will likely decline when the areas of suitably cold habitats shrink.

All four species that can be clearly distinguished by morphology have relatively northern distributions and are especially common in the mountain range and the lowlands of the far north (Fig. 3). The mapped distributions clearly underestimate the frequency of the species in Norway, since the mapped occurrences are based on S material only and the distribution of members of the genus *Oncophorus* is much wider according to ‘Artskart’ (<https://artskart.artsdatabanken.no/>; accessed 9 Feb. 2016).

All four species occur with different frequencies in several humid to wet habitats (Fig. 4). *Oncophorus elongatus* obviously prefers organic substrates, such as decomposing wood and peaty soil in mires, whereas *O. virens* is clearly a species of brook and lake shores, and wet rocks, and is the only species that is often found in late snow-beds. The two remaining species are most frequently found in mire habitats, but are relatively abundant also on brook and lake shores, and wet rocks. *Oncophorus elongatus* and *O. wahlenbergii* occur in relatively base-poor environments, whereas *O. virens* and *O. integerrimus* sp. nov. are mostly found in base-rich to calcareous habitats. Whether entities within species that display clear intraspecific molecular variation also differ from each other in habitat preferences should be explored when molecular information exists for additional specimens.

From a biodiversity and conservation point of view the cryptic diversity in *Oncophorus* deserves serious attention (Hedenäs 2016). A fuller sampling of *O. virens*, *O. elongatus*, and *O. wahlenbergii* is required to understand their cryptic and semi-cryptic diversities, as well as intrinsic geographic and habitat components. Additionally, this would possibly allow the discovery of morphologically stable characters to distinguish at least *O. wahlenbergii* B. However, at the present state of knowledge, and considering the wish by most biologists to be able to distinguish species by morphology, four ‘species’ of *Oncophorus* are here recognized for Scandinavia.

## Acknowledgements

I thank Bodil Cronholm for her excellent laboratory work, L. Ellis at BM for a loan of type material, and T.L. Blockeel for a gift and a loan of *O. dendrophilus* material. Two reviewers provided comments that significantly improved the text. Financial support for the molecular work was received from the Swedish Taxonomy Initiative (dha 2014-79 4.3).
