Abstract. *Canthon (Peltecanthon)* is revised in this work. The subgenus now includes four species: *C. (P.) staigi* (Pereira, 1953), *C. (P.) haroldi* nom. nov., *C. (P.) splendidus* Schmidt, 1922 and *C. (P.) terciiae* sp. nov. All species occur in the Atlantic Forest. Maps, natural history information, specimen data and illustrations are provided.

Keywords. Dung beetles, Atlantic Forest, new species, rollers, *Canthon staigi*, *Canthon splendidus*, *Canthon sulcatus*.

Nunes L.G. de O.A., Nunes R.V. & Vaz-de-Mello F.Z. 2020. Taxonomic revision of the South American subgenus *Canthon (Peltecanthon)* Pereira, 1953 (Coleoptera: Scarabaeidae: Scarabaeinae: Deltochilini). *European Journal of Taxonomy* 594: 1–27. <https://doi.org/10.5852/ejt.2020.594>

Introduction

There are nine subgenera described in the genus *Canthon* Hoffmannsegg, 1817: *Canthon* s. str. (48 species); *Glaphyrocantthon* Martínez, 1948 (42 spp.); *Peltecanthon* Pereira, 1953 (3 spp.), *Pseudepilissus* Martínez, 1954 (14 spp.); *Goniocantthon* Pereira & Martínez, 1956 (3 spp.); *Nesocantthon* Pereira & Martínez, 1956 (3 spp.); *Boreocantthon* Halffter, 1958 (15 spp.); *Francmonrosia* Pereira & Martínez, 1959 (6 spp.); and *Trichocantthon* Pereira & Martínez, 1959 (1 sp.). Beside these, 22 species do not have defined subgenera and are considered *incertae sedis* in the genus (Halffter & Martínez 1977; Cupello & Vaz-de-Mello 2018).

The subgenus *Peltecanthon* was first described as a full genus and was later reduced to a subgenus of *Canthon* by Halffter & Martínez (1977). It included the following three described species: *Canthon staigi* (Pereira, 1953), which is the type species of the subgenus; the so-called ‘*Canthon sulcatus* Perty, 1830’, which was placed in the subgenus by Pereira (1953); and *Canthon splendidus* Schmidt, 1922, which was transferred under the erroneous name of ‘*Canthon auricollis*’ by Halffter & Martínez (1977) and later corrected by Vaz-de-Mello & Cupello (2018a).

The last revisions of *Peltecanthon* were published in the 1970s. Since then, important updates on the morphological delimitation and distribution of the species of *Peltecanthon* have provided new insights into the taxonomy of this subgenus (e.g., Ferreira-Neto *et al.* 2017). Currently, it is necessary to establish in an objective and comparative way the characters that differentiate these species, as well as to update the information about their distributions and to correct possible nomenclatural misunderstandings. With access to a new range of material related to these species, our objective was to conduct a taxonomic review of the subgenus *Peltecanthon*.

Material and methods

A total of 1050 specimens from the following institutions and collections were examined (curator in parenthesis):

- CEAH = Coleção Entomológica Adolph Hempel, Instituto Biológico, São Paulo, state of São Paulo, Brazil (Sérgio Ide)
- CEMT = Setor de Entomologia da Coleção Zoológica da Universidade Federal de Mato Grosso, Departamento de Biologia e Zoologia, Cuiabá, Mato Grosso, Brazil (Fernando Z. Vaz-de-Mello)
- MNHN = Muséum national d’histoire naturelle, Paris, France (Olivier Montreuil and Antoine Mantilleri)
- MZSP = Museu de Zoologia, Universidade de São Paulo, São Paulo, São Paulo, Brazil (Carlos Campaner and Sônia Casari)
- NHMUK = The Natural History Museum, London, United Kingdom (Max Barclay). The code “BMNH” is used on the specimen labels
- NMW = Naturhistorisches Museum Wien, Vienna, Austria (Harald Schillhammer)
- SMTD = Senckenberg Naturhistorische Sammlungen, Dresden, Germany (Klaus-Dieter Klass and Olaf Jaeger)
- ZSM = Zoologische Staatssammlung München, Munich, Germany (Lars Hendrich, Michael Balke and Katja Neven)

Lists of examined material were separated into type material and non type material. For type material, labels are transcribed *ipsis litteris* (text between double quotation marks) and are separated by ‘/’, with species names in italics. After the information from each type label, label colour or main characteristics are briefly explained in parentheses. In non type material lists, information from labels was organized as follows: country name, in capital letters (e.g., BRAZIL); department or state name in bold letters (e.g., **Rio de Janeiro**); the number of males (♂ or ♂♂) and females (♀ or ♀♀); municipality and/or locality (when available); coordinates; date (e.g., 3 Mar. 1986); collector (leg.); collection techniques and environmental/ecological information (when available, collection techniques or other details were transcribed in the original language found on the label; text between double quotation marks); and the repository (e.g., CEMT means deposited in CEMT collection).

Morphological analysis and comparisons were conducted using a Leica stereo microscope model EZ 4. The programs Photo Filter and Combine ZP were used for editing of the images. Maps were constructed

using Diva Gis, ver. 7.5, while the endophallus structure was drawn using a stereo microscope with a Nikon SMZ 800 camera lucida.

The extraction, treatment and preservation of internal sac sclerites follows the procedure described by Zunino (1978). Internal sac sclerite nomenclature followed Tarasov & Solodovnikov (2011). External morphology terminology was based on recently published taxonomic and phylogenetic works dealing with the tribe Deltochilini and/or *Canthon* (Vaz-de-Mello *et al.* 2011; Tarasov & Génier 2015).

Abbreviations

A = axial sclerite
FLP = fronto-lateral peripheric sclerite
MP = medial peripheric sclerite
SA = subaxial sclerite
SRP = superior right peripheral sclerite
T = temones

Canthon (Peltecanthon) – Halffter & Martínez 1977: 75 — Vaz-de-Mello 2000: 191 (species list) — Medina *et al.* 2003: 24, 38, 45 — Vaz-de-Mello *et al.* 2011: 52 (key) — Cupello & Vaz-de-Mello 2018: 18, 46 — Vaz-de-Mello & Cupello 2018a: 46.

Type-species

Peltecanthon staigi Pereira 1953, by original designation (Pereira 1953).

Diagnosis

Among the Scarabaeinae, the tribe Deltochilini features the following characters: hind wing vein radio posterior 1 (RP1) with a small basal appendix and radio anterior 4 (RA4) clearly thinner than RP1 and basally fused with RP1 (Tarasov & Dimitrov 2016). Among the Deltochilini, *Canthon (Peltecanthon)* can be differentiated by the following combination of characters: shiny pronotum and elytral disc, without tubercles or lateral carinae; ventral surface of the metafemora without anterior margin; and metafemora with elongated base, giving the femur a claviform shape (Halffter & Martínez 1977; Vaz-de-Mello *et al.* 2011).

Key to the species of *Canthon (Peltecanthon)*

1. Dorsal surface with blue, green and red metallic reflections (Figs 1A, 3A, 5A, 7A). Metafemur base narrow, claviform, ventral surface without anterior margin (Figs 1B, 3B, 5B, 7B) 2 Subgenus *Peltecanthon* Pereira, 1953
 - Dorsal surface having other colours and reflections. Metafemur base wide, not claviform, ventral surface with or without anterior margin other *Canthon* groups and subgenera
2. Dorsal surface with green metallic reflections (Fig. 3A). Metafemora with posterior longitudinal groove at their basal third (Fig. 3B). Hypomera lacking transverse carina (Fig. 3C). Pygidium basal margin (which separates it from pro-pygidium) lacking carina (Fig. 3D). Paramere apical margin sinuous (Fig. 4A). Brazilian Atlantic Forest (from Bahia to Rio de Janeiro)
..... *Canthon (Peltecanthon) haroldi* nom. nov.
 - Dorsal surface with blue, green and/or red reflections (Figs 1A, 5A, 7A). Metafemur base is smooth (Fig. 7A) or with punctures (Figs 1A, 5A), always lacking longitudinal groove. Hypomera with transverse carina (Figs 1C, 5C, 7C). Pygidium basal margin (which separates it from pro-pygidium) carinate (with a V-shaped projection) (Figs 1D, 5D, 7D). Paramere apical margin straight, sub-straight or sinuous 3
3. Elytra and pronotum of different colours; dorsal surface of elytra blue, pronotum with green and red reflections (Fig. 5A). Hypomera with transverse carina strongly marked and interrupted near external margin (Fig. 5C). Pygidium basal margin with weak carina (Fig. 5D). Paramere apical margin strongly sinuous (Fig. 6A). Southern Brazilian Atlantic Forest (Minas Gerais, Espírito Santo and Rio de Janeiro) *Canthon (Peltecanthon) splendidus* Schmidt, 1922
 - Elytra and pronotum of equal colours; dorsal surface of elytra and pronotum blue, red or green. Hypomera with transverse carina finely marked and interrupted at mid-portion (e.g., Figs 1C, 7C). Pygidium basal margin with strong carina. Paramere apical margin sub-straight (e.g., Figs 2A, 8A) .
..... 4
4. Dorsal surface with blue or green reflections, pronotum and elytra of same colour (Fig. 1A). Metafemur with basal portion punctures (Fig. 1B). Atlantic Forest in Brazil (from Pernambuco to Paraná), Paraguay and Argentina *Canthon (Peltecanthon) staigi* (Pereira, 1953)
 - Dorsal surface with red or light green reflections, pronotum and elytra of same colour (Fig. 7A). Metafemur with basal portion smooth, lacking punctures (Fig. 7A). Northern Brazilian Atlantic Forest (Rio Grande do Norte, Paraíba, Pernambuco and Sergipe)
..... *Canthon (Peltecanthon) terciae* sp. nov.

Canthon (Peltecanthon) staigi – Halffter & Martínez 1977: 75 (taxonomic remarks) — Medina *et al.* 2003: 29–30, 34–35, 38–39, 42–43, 45–47, 50, 52, 54, 57, 64, 66 — Vaz-de-Mello *et al.* 2011: 52, fig. 31 (key) — Cupello & Vaz-de-Mello 2018: 46 — Vaz-de-Mello & Cupello 2018a: 46.

Diagnosis

In the subgenus, *Canthon staigi* can be distinguished by the following combination of characters. Dorsally elytra and pronotum with blue or green colouration and blue and green reflections (Fig. 1A). Metafemora with several punctures at base, with no groove (Fig. 1B). Hypomere with thin transverse carina between the anterior and posterior portions, projecting to the median region, anterior region not excavated (Fig. 1C). Propygidium with strong V-shaped carina between pygidium and propygidium (Fig. 1D). Parameres flattened in lateral view (Fig. 2A); truncated apex, sub-straight, never sinuous; slightly rounded upper angle; straight lower angle. In dorsal view (Fig. 2B): membranous portion separates the parameres, wider in the central region and narrower at the base and apex. Internal sac (Fig. 2C–D) with peripheral fronto-lateral sclerite (FLP) involving axial sclerite (A), both structures forming a complex with a central duct, wider at the base, gradually narrowing toward the apex, which is much finer; subaxial sclerite (SA) lateral to the FLP + A complex; peripheral medial sclerite (MP) lateral in relation to FLP + A, this with the sharper part passing within a semiduct formed by MP; MP with a central denticle at the inner margin (Fig. 2C); superior right peripheral sclerite (SRP) circular and with semi-circular lateral prolongation.

Material examined

Holotype

BRAZIL • ♂, holotype of *Peltecanthon staigi* (Pereira, 1953); 1 (red label, black border) “HOLOTIPO” / 2 (white label, black margins) “Espírito Santo, Col. Mutum, 16849” / 3 (white label, black margins) “*Canthon smaragdulus* ♂, Lüd. det. 14” / 4 (white label, black margins) “*Peltecanthon staigi*, gen. sp. n. ♂, P. Pereira det. 953” / 5 (white label) “05536 MZSP”.

Remarks

This species was described by Pereira (1953) in the same publication as the description of the subgenus, for which the author simultaneously designated it as the type species.

Distribution

Atlantic Forest, from Pernambuco to Paranaguá, southeast of the state of Paraná. In the literature there are records for Argentina and Paraguay (Pereira & Martínez 1956; Martínez 1959; Halffter & Martínez 1967), but we have not examined any specimens from these localities (Fig. 10).

Canthon (*Peltecanthon*) *haroldi* nom. nov.

Diagnosis

In the subgenus, *Canthon haroldi* can be separated by the following combination of characters. Elytra and pronotum dorsally green with shades of yellow and red (Fig. 3A). Metafemora with sulcus extending from the base and up to $\frac{1}{3}$ of the total femur length (Fig. 3B). Hypomere with no carina between the anterior and posterior portion (Fig. 3C). Propygidium with uniform line between pygidium and propygidium, without any central carina (Fig. 3D). Parameres flattened in lateral view (Fig. 4A); slightly sinuous apex never strongly sinuous or truncated, with a slight depression near the upper angle; rounded upper angle; lower angle slightly less than 90°. In dorsal view (Fig. 4B): membranous portion separates the parameres, wider in the central region and narrower at the base and apex. Internal sac (Fig. 4C–D) with the peripheral fronto-lateral sclerite (FLP) involving the axial sclerite (A), with the two structures forming a complex with a central duct, wider at the base, becoming abruptly tapered toward the apex; subaxial sclerite (SA) absent; peripheral medial sclerite (MP) lateral in relation to FLP + A, this with the sharper part passing within a semiduct formed by MP; MP with a central appendage at the inner margin (Fig. 4C); superior right peripheral sclerite (SRP) circular and with lateral prolongation.

Remarks

This species has a complex and confusing nomenclatural history. The name *Canthon prasinus* was first established by Klug (1833) for a new species from Madagascar. However, Klug's species was not described in a suitable genus since *Canthon* is entirely Neotropical in occurrence. Four years later, Dejean (1836) transferred that species to his new genus *Epilissus*, of which Reiche (1841) subsequently designated it as the type species.

More than three decades after Reiche's work, Harold (1867a) established a primary junior homonym *C. prasinus* for a Brazilian species that, according to Harold (1868), had been misidentified as *Canthon sulcatus* Perty, 1830 by Castelnau (1840); Perty's actual species, in fact, belonged to *Canthidium* Erichson, 1847, where it had already been transferred by Harold (1867b) and still remains (Cupello 2018). In his 1869 catalogue of the world Scarabaeinae, Harold (1869: 992) maintained that stance by including '*C. sulcatus* Castelnau' as a junior synonym of *C. prasinus* Harold. Harold (1875) used *C. prasinus* as valid again in his list of the dung beetles of the municipality of Cantagalo, Rio de Janeiro state, Brazil.

Gillet (1911) listed *Canthon prasinus* Harold and '*Canthon sulcatus* Castelnau' as valid species; however, in the same work, he also considered the two names as synonyms.

In most of the 'recent' literature, only one author followed Gillet's view (Blackwelder 1944), while many others followed Schmidt's (Balthasar 1939; Pereira 1953; Vulcano & Pereira 1964), but all those authors were wrong. This included the descriptive work of the new South American genus *Peltecanthon* (Pereira 1953).

Applying Article 23.9.5 of the International Code of Zoological Nomenclature, there are arguments that both names can be preserved, since they have not been considered congeneric after 1899. However, to invoke that Article, we would have to consider that *C. prasinus* is currently in use, which is not the case, or that *C. sulcatus* was first published by Schmidt, not Castelnau (which is also not the case). Considering this context, we propose *Canthon haroldi* as a new replacement name, in homage to Edgar Von Harold, who made the most correct evaluation regarding the application of those names, and was misinterpreted by subsequent authors.

Distribution

Atlantic Forest in the Brazilian coast, in the states of Bahia, Espírito Santo, Minas Gerais and Rio de Janeiro (Fig. 10).

Canthon (*Peltecanthon*) *splendidus* Schmidt, 1922

Figs 5–6

Canthon splendidus Schmidt, 1922: 68, 81, 93.

Canthon splendidus – Balthasar 1939: 209 (key) — Halffter & Martínez 1977: 76 (as junior synonym of *Canthon auricollis*).

Canthon (*Peltecanthon*) *splendidus* – Vaz-de-Mello & Cupello 2018a: 46; 2018b: 67–68, figs 101–102.

Diagnosis

Canthon splendidus can be distinguished by the following combination of characters: elytra and pronotum with different colouration, with pronotum bright with golden or red reflections, and elytra blue-green (Fig. 5A). In the legs the metafemora with no groove at base (Fig. 5B). Hypomere with a strong excavation in the anterior region, with a thick transverse carina between the anterior and posterior portion projecting to near the lateral margin and never only up to the median region (Fig. 5C). Propygidium with a moderate carina near pygidium border (Fig. 5D). In lateral view (Fig. 6A) parameres flattened; a strongly sinuous apex, never slightly sinuous or truncated, with a deep excavation near the upper angle; rounded upper angle; lower angle much less than 90°. In dorsal view (Fig. 6B): membranous portion separates the parameres, wider in the central region and narrower at the base and apex. Internal sac (Fig. 6C–D) with peripheral fronto-lateral sclerite (FLP) involving the axial sclerite (A), where the two structures form a complex with a central duct, wider at the base, with a subtle tapering in the median region and sharp apex; subaxial sclerite (SA) absent; peripheral medial sclerite (MP) lateral to FLP + A, tapered region with the sharper part passing within a semiduct formed by MP; superior right peripheral sclerite (SRP) circular and with lateral prolongation.

Redescription

Male

MEASUREMENTS. Body length (except the head): 9.5 mm, pronotum width: 6.0 mm.

COLOUR. Dorsally, pronotum and elytra with distinct colouration elytra dark blue, pronotum green with bright red and yellow reflections (Fig. 5A).

HEAD. Green with bright yellow. Dorsal surface with small spots equally spaced. Two clypeal teeth triangular, with rounded apex, separated by a V-shaped emargination, with two dorsal tufts of setae and two ventral tufts. Clypeo-genal suture present (Fig. 5A).

PRONOTUM. Pronotal disc smooth, green with small bright red and yellow spots, equally spaced; Anterior angles acute (Fig. 5A).

ELYTRA. Striae narrow, always distinct; interstriae wide, flat.

HYPOMERON. Dark blue and black, chagrinated microsculpture; sparse setae present on anterior portion and anterolaterally; strong transverse carina along $\frac{2}{3}$ of the whole length; anterior portion little excavated, with prominent teeth anterolaterally (Fig. 5C).

LEGS. Protibiae with three teeth; protibial spur flattened dorsoventrally, bifid, with medial and lateral bifurcation, triangular, different sizes, asymmetrical (Fig. 5E). Meso- and metafemora with ventral side lacking anterior and posterior margin; metafemora with a narrower and longer base, claviform; metafemoral ventral surface with spots at the base (Fig. 5B).

ABDOMEN. Ventrites with few setae, chagrinated, black and blue.

PYGIDIUM. As wide as long; blue with bright green and yellow; basal margin little expanded (Fig. 5D).

PARAMERES. Flattened laterally; on lateral view, apical portion with a long sinuosity; on dorsal view, central membranous portion enlarged in the centre (Fig. 6A–B).

INTERNAL SAC. Fronto-lateral peripheral sclerite (FLP) involving axial sclerite (A), forming a central duct with spiniform apex; subaxial sclerite (SA) absent; medial peripheral sclerite (MP) semicircular, widely emarginated, with the internal margin with a lobe on the extremity (without central tooth); external margin sinuous with a lobe on the extremity, lobes separated by a U-shaped margin; apex of FLP + A involved by MP; superior right peripheral sclerite (SRP) circular with lateral prolongation in the dorso-ventral direction (Fig. 6C–D).

MORPHOLOGICAL VARIATION. Body length (except the head) ranges from 9.5 mm to 12 mm; pronotum width from 6 to 7.5 mm. Pronotum with bright reflections, according to the viewing angle, between different intensities of green, red and yellow.

Female

LEGS. Protibial spur with medial and lateral bifurcation, triangular, equal in size, symmetrical (Fig. 5F).

Remarks

For a long time, this species was identified as *Canthon auricollis* Redtenbacher, 1868, but the examination of the type specimens of both nominal species allowed Vaz-de-Mello & Cupello (2018a) to conclude that, in fact, the latter name refers to another species belonging to *Canthon* s. str., closely related to *C. lividus* Blanchard, 1846. It is an insect that can be considered very rare and can only be collected at altitudes usually over 1000 m. The predominance of pronotal sheen varies from golden yellow to red.

Distribution

High altitude in the Atlantic Forest along the coast of Brazil, in the states of Minas Gerais, Espírito Santo and Rio de Janeiro (Fig. 10).

Canthon (Peltecanthon) terciæ sp. nov.

urn:lsid:zoobank.org:act:C9F36543-7F9D-4498-ABAF-3784D46A2E60

Figs 7–9

Diagnosis

Canthon terciæ sp. nov. can be distinguished by the following combination of characters: elytra and pronotum dorsally red or green reddish (Fig. 7A). Legs with flat metafemur at the base, with no punctures or groove (Fig. 7B). Hypomerion with thin transverse carina between the anterior and posterior portion, projecting to the median region, never near the lateral margin, anterior region without excavation (Fig. 7C). Propygidium with strong carina near pygidium edge (Fig. 7D). Parameres, in lateral view (Fig. 8A): flattened; truncated apex, sub-straight, never sinuous; slightly rounded upper angle; lower right angle. In dorsal view (Fig. 8B): membranous portion separating the parameres, wider in the central region and narrower at the base and at the apex. Internal sac (Fig. 8C–D). Peripheral fronto-lateral sclerite (FLP) involving the axial sclerite (A), the two structures form a complex with a central duct, wider at the base, which gradually tapers to the apex, which is much thinner; subaxial sclerite (SA), smaller than in *C. staigi*, lateral to the FLP + A complex; peripheral medial sclerite (MP), without central dentin at the inner margin, distal to A, lateral in relation to FLP + A tapered region, with the sharper part passing within a semiduct formed by MP; superior right peripheral sclerite (SRP) with lateral angular prolongation.

Etymology

This species is named in honour of Dr Tercia Vargas dos Santos, who developed phylogeographical studies with the subgenus *Peltecanthon* and reinforced our taxonomic decision.

Description

Holotype (male)

MEASUREMENTS. Body length (except the head): 10.0 mm, pronotum width: 7.0 mm.

COLOUR. Dorsally red with bright green. Ventrally green with bright red (Fig. 7A).

HEAD. Red with bright green. Dorsal surface with small spots equally spaced. Two clypeal teeth triangular, with rounded apex, separated by a V-shaped emargination, with two tuft of setae dorsally and two tufts ventrally. Clypeo-genal suture present (Fig. 7A).

PRONOTUM. Pronotal disc smooth, red, bright, with small punctures equally spaced. Anterior angles acute (Fig. 7A).

ELYTRA. Striae narrow, distinctly impressed. Interstriae wide, flat (Fig. 7A).

HYPOMERON. Green, chagrinated microsculpture. Sparse setae present on anterior portion and anterolaterally. With thin transverse carina between the anterior and posterior portion projecting to the median, region anterior not excavated (Fig. 7C). Anterior portion flat, with a little tooth anterolaterally (Fig. 7C).

LEGS. Protibiae with three teeth. Protibial spur flattened dorsoventrally, bifid, with medial and lateral triangular bifurcation with different sizes, asymmetrical (Fig. 7E). Meso- and metafemoral ventral side lacking anterior and posterior margin. Metafemora with a narrower and longer base, claviform (Fig. 7B).

ABDOMEN. Venterite glabrous, chagrinated. Black and green.

PYGIDIUM. As wide as long. Red with bright green. Basal margin expanded, forming a strong carina in V-form between pygidium and propygidium.

PARAMERES. Flattened laterally. On lateral view, apical portion ventrally truncated, dorsally a little curve. In dorsal view, central membranous portion enlarged in the centre (Fig. 8A–B).

INTERNAL SAC (Figs 8–9). Fronto-lateral peripheric sclerite (FLP) involving axial sclerite (A) forming a central duct with spiniform apex, very slim. Subaxial sclerite (SA) small, lateral to FLP + A complex and

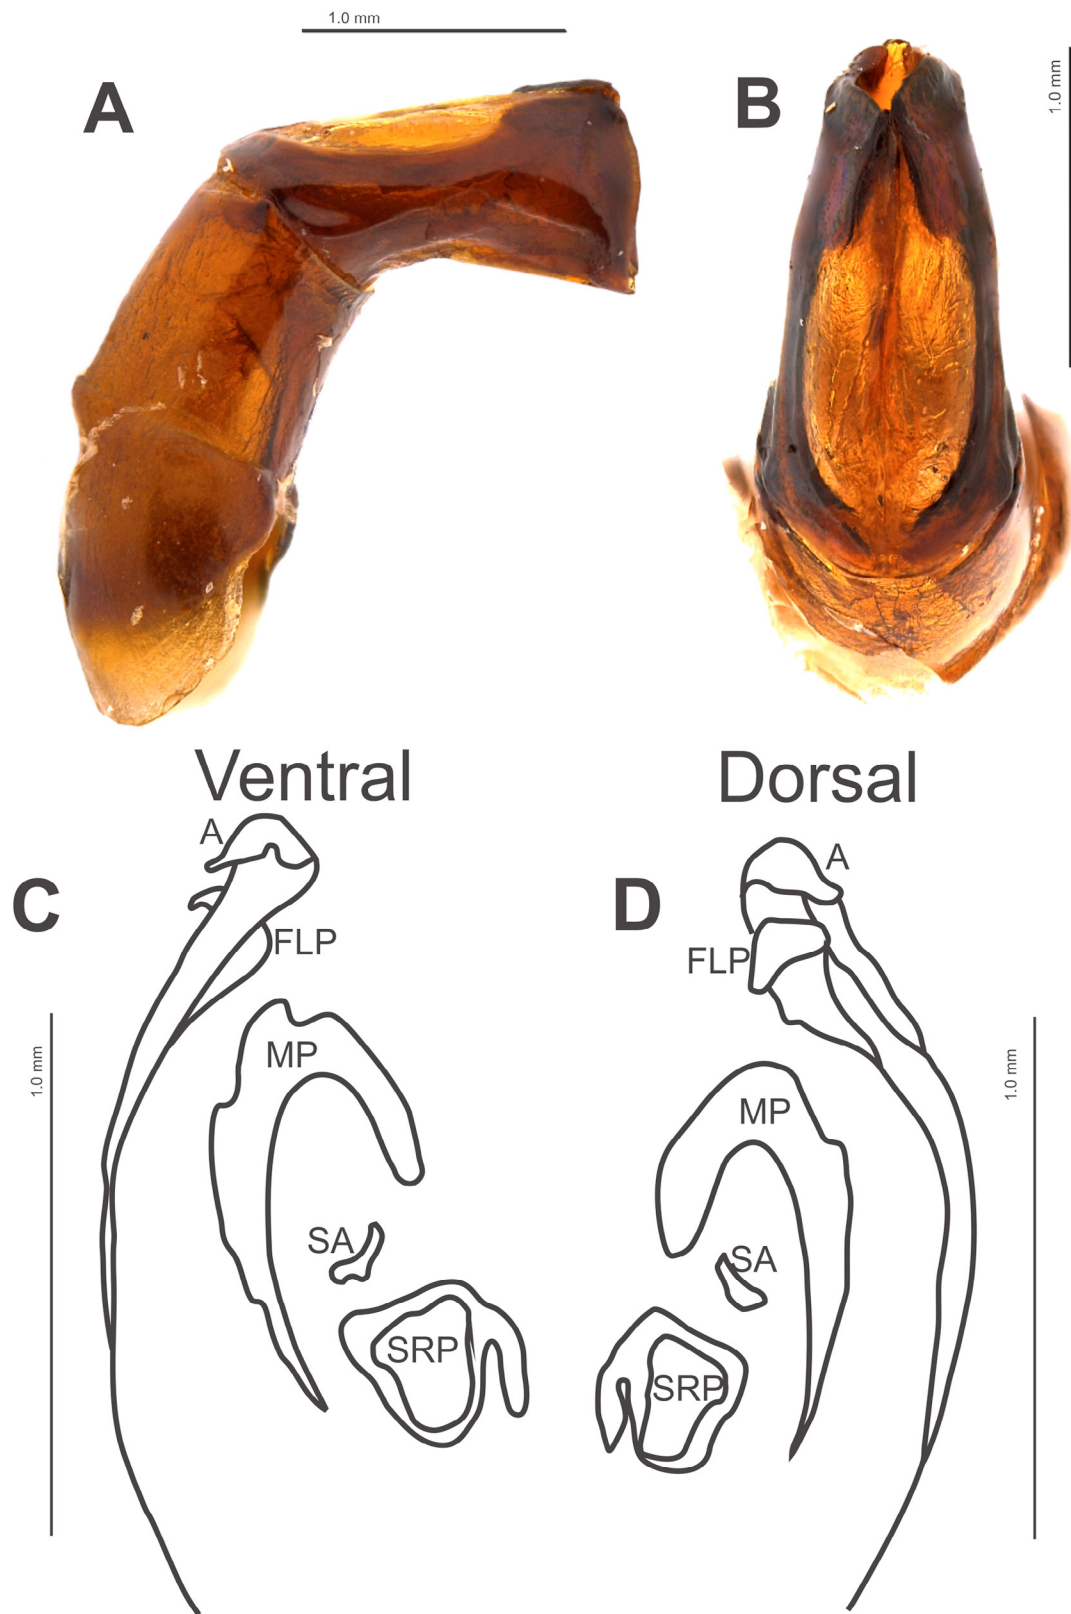

Fig. 8. *Canthon (Peltecanthon) terciæ* sp. nov., paratype, ♂, Rio Grande do Norte, Baía Formosa, Mata Estrela (CEMT). **A.** Parameres lateral view. **B.** Parameres dorsal view. **C.** Internal sac ventral view. **D.** Internal sac dorsal view. Abbreviations: see Material and methods.

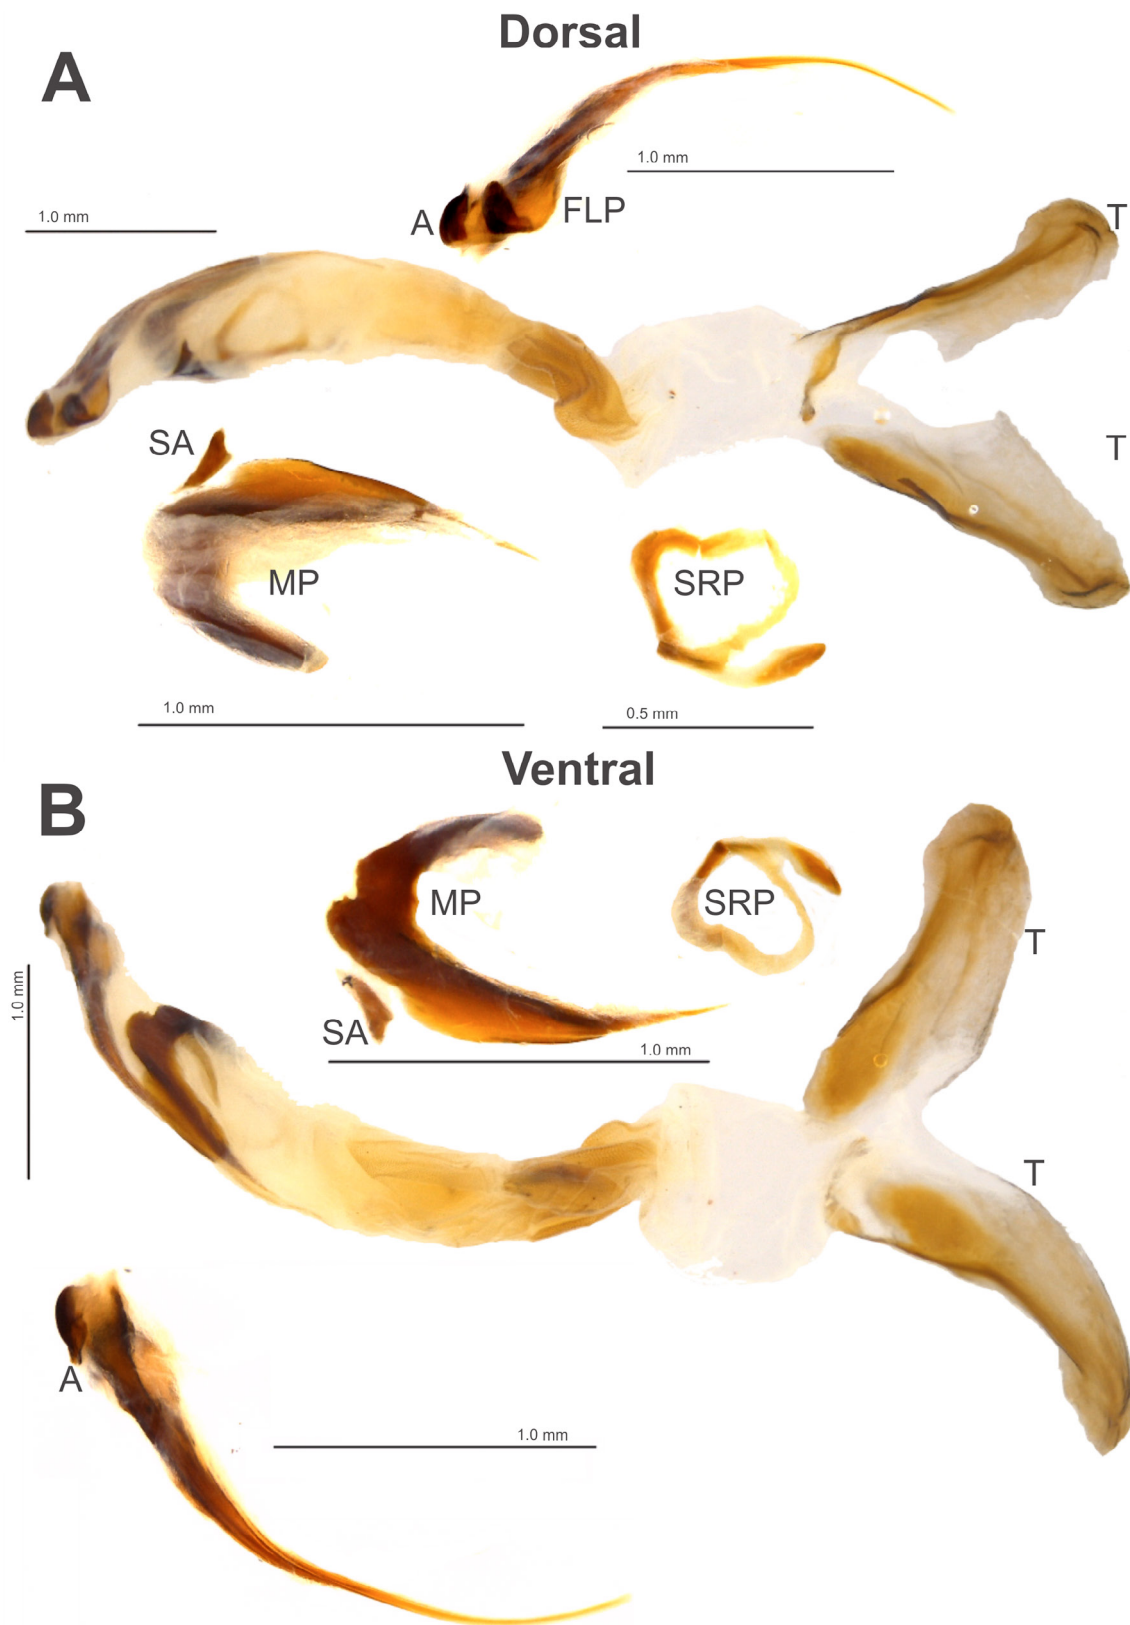

Fig. 9. *Canthon (Peltecanthon) terciae* sp. nov., paratype, ♂, Rio Grande do Norte, Baía Formosa, Mata Estrela (CEMT). Position of the internal sac sclerites. **A.** Dorsal view. **B.** Ventral view. Abbreviations: see Material and methods.

MP, dorsal to all sclerites. Medial peripheric sclerite (MP) semicircular, widely emarginated, with the internal margin continue (without central tooth), margin external sinuous; Apex of the FLP + A complex involved by MP. Superior right peripheral sclerite (SRP) circular, with lateral prolongation in the dorso-ventral direction.

MORPHOLOGICAL VARIATION. Body length (except the head) ranges from 8.5 to 11.5 mm; pronotum width from 6 to 7.5 mm. Colour: dorsally green with bright red. Legs: metafemoral ventral surface not completely smooth, with some punctures.

Female

LEGS. Protibial spur with medial and lateral bifurcation triangular with equal sizes, symmetrical (Fig. 7F).

Remarks

This new species is much more similar to *C. staigi* than to the other two species of *Peltecanthon*. The differences between them are very subtle, and there are great morphological similarities between them, in the main characters that differentiate the species of this subgenus; the main differences observed are in the sclerites of the internal sac (exactly in MP). In addition to the sclerite, these species (*C. staigi* and *C. terciae* sp. nov.) can be differentiated only by the characters of the dorsal colour and base of the metafemur, without any need for dissection.

Geographic distribution

Northern Brazilian Atlantic Forest, in the states of Rio Grande do Norte, Paraíba, Pernambuco and Sergipe (Fig. 10).

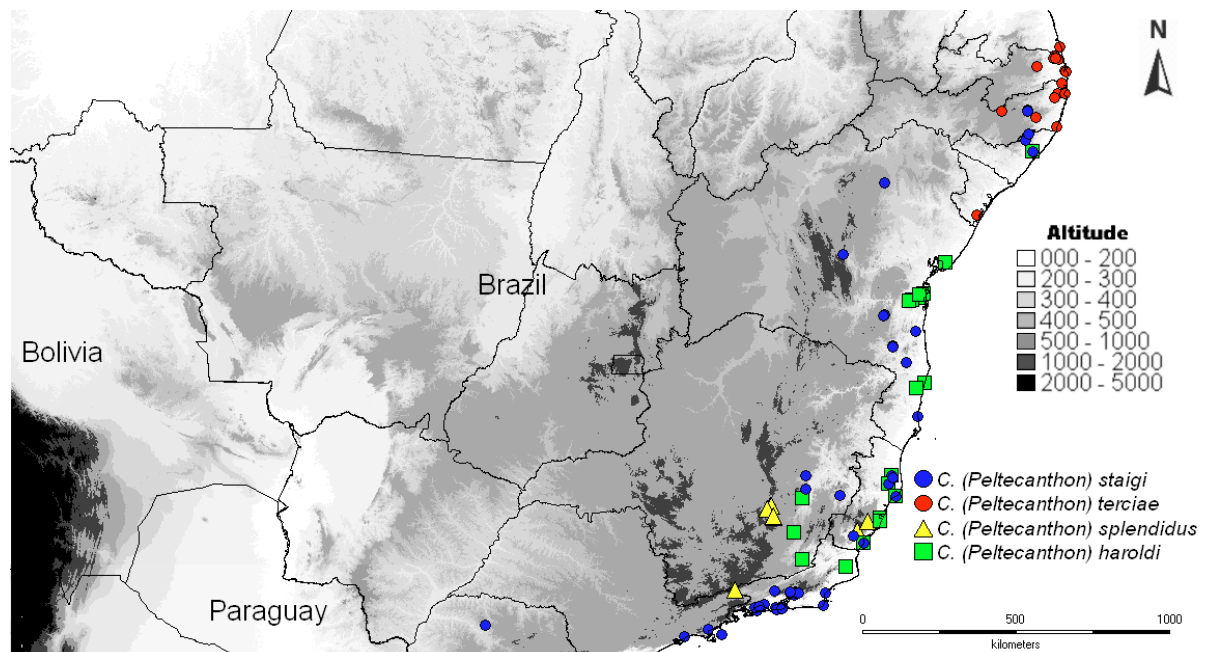

Fig. 10. Distribution map for species of *Peltecanthon*: *C. (P.) staigi* (Pereira, 1953) (blue circle); *C. (P.) haroldi* Harold, 1867 nom. nov. (green square); *C. (P.) splendida* Schmidt, 1922 (yellow triangle); *C. (P.) terciae* sp. nov. (red circle)

Discussion

Phylogenetic relationships between the groups within *Canthon* are still poorly understood. Despite the fact that Medina *et al.* (2003) placed *Peltecanthon* near *Goniocanthon*, their analysis does not consider molecular data and lacks some important species. However, there is a close external resemblance between the two subgenera (*Peltecanthon* and *Goniocanthon*), but we cannot conclude at this point whether this resemblance is due to morphological convergence or common ancestry.

However, despite their colour and dorsal resemblance, one can readily distinguish the two genera by looking at the pygidium (flat in *Peltecanthon*, strongly convex in *Goniocanthon*) and metafemora (claviform in *Peltecanthon*, regular in *Goniocanthon*) (Nunes *et al.* 2018). Both characters are very useful in avoiding misidentification, especially between *C. (Peltecanthon) staigi* and *C. (Goniocanthon) smaragdulus* (Fabricius, 1781), both blue-coloured species from the Brazilian Atlantic Forest.

At first glance, *Peltecanthon* species diversity is related to historically stable areas in the Atlantic Forest, as defined by Carnaval & Moritz (2008). Recent published data on Scarabaeinae (genus *Dichotomius* Hope, 1837) also reveal that the northern part of the Atlantic Forest harbours several endemic species (Valois *et al.* 2017). Extra attention is needed to remnants of Atlantic forest: first, because of a considerable number of new endemic species awaiting description around Alagoas, Pernambuco and Sergipe forest remnants. Second, these remnants are in great danger, mainly from anthropogenic activities (Zwiener *et al.* 2017).

Little information is available on the ecology and behaviour of *Peltecanthon* from labels and from the published literature. In general, all species seem to be attracted to mammalian faeces and carrion. The occurrence of *C. staigi* does not seem to depend on well-preserved habitats, and it is sometimes the ‘last’ Scarabaeinae species in heavily disturbed environments (pers. obs. RVN). Of the other species, *C. splendidus* is the rarest, *C. terciæ* sp. nov. appears to be quite common in parts of the northeast coast and *C. haroldi* is very abundant in the region of Linhares in Espírito Santo.

Further descriptive taxonomic work on *Canthon* and other Deltochilini groups is required. It is imperative to develop morphological and molecular phylogenies to provide better classifications, and a better understanding of Neotropical Scarabaeinae systematics and evolution. However, alpha-taxonomy description works are still essential to elucidate, at least, the diversity of the Atlantic Forest Scarabaeinae.

Acknowledgments

LGOAN (23108.096582/2015-11) and RVN (23108.036500/13-3) received CAPES grants. FZVM receives financial support from CNPq (process nº 302997/2013-0, 484035/2013-4, 440604/2015-0, 568005/2014 PRONEM, 248299/2012-3, 405697/2013-9), Synthesis (GB-TAF-3855), INCT-CENBAM/CNPq and Rede ComCerrado/MMA. We thank all curators named in the methods section, and Mario Cupello for providing geographical records.
